No. 1.

NOTES AND COMMENTS.

Suffragette **Prison Treatment** **All Round.** WHATEVER views we may hold as to the wisdom of the tactics of the militant suffragette, there can be no doubt whatever as to her persistency and self-devotion. She has presented administrative government with one of the hardest nuts it has been called upon to crack for many generations. In spite of the fierce public resentment stirred up by the recent window-smashing campaign, Mr. and Mrs. Pethick-Lawrence and Mrs. Pankhurst, the head-centres, so to speak, of the movement, have been released after a short spell of prison duration. The weapon that beats the Government is apparently the hunger strike. Mrs. Pankhurst refuses food, she is forcibly fed, the process is found to be not unattended with danger owing to the state of her heart, and straightway her prison doors are opened and she walks out a free woman. In other words, she has determined the length of her own service in prison. If justice of this kind is to be dispensed, well and good, but let it apply all round. Let all window smashers be treated as first-class offenders, and should they refuse food let them free, unless their bodily condition be sound enough to withstand the rigours of artificial feeding. The militant suffragette maintains that her offence is political. She claims that motive is the main factor in assessing the degree of offence of window smashing. Well, if a social disability, owing to alleged shortcoming in the laws, is in future to justify violence of that kind, the police magistrates will find their hands full of such cases, and first-class wings must be added to our gaols.

Prison Treatment. FROM the point of view of health there is much to be said to the extension of first-class accommodation to all prisoners, or—to put the matter in another way—to raise materially the standards of food and environment in our prisons. If amelioration be needed in the case of the window-smashing suffragette, it is no less needed in that of other prisoners whose criminal motives may be less obviously altruistic and whose outside friends are less politically powerful. Our criminal system, in spite of recent reforms, is still brutal and unscientific, especially as regards summary punishment. The folly of a system that shuts up a man for days, weeks or months for some trifling offence against property, involving perhaps the value of a few pence, is fairly self-obvious to a little inquiry. The offender is branded for life, loses his situation, his family probably become chargeable to the parish, the cost of his prosecution and his maintenance in prison is thrown upon the taxpayers, and the person whose goods have been lost has no compensation! Lastly, while in prison he is fed in a way that reduces him in weight, and

he is discharged to obtain a fresh footing in the world with the handicap of an enfeebled body. But, nevertheless, if this be right for the ordinary offender against property, it can hardly be wrong in the case of any window smasher, regardless of sex or motive. It is the window that counts.

In Defiance of the Law. It is the fashion nowadays to defy the law. One has only to glance round upon current events to recognise the truth of that proposition.

There are the suffragettes assaulting the Prime Minister in his own house, the Ulster party threatening armed resistance to Home Rule in Ireland, the Anglican Church asserting its right to ostracise from communion persons married according to statute law, while the man in the street protests energetically against this, that or the other Act that may not suit particular views. To a limited extent this sort of resistance is wholesome and desirable, but beyond a certain point, which it is not always possible to define with precision, it enters the danger zone. When the dockers of the metropolis assert their dissatisfaction against certain social conditions by strikes and general violence, society is at once faced by the danger of starvation and of the suspension of law and order. Clearly if it be right for one set of citizens to defy the law it can hardly be wrong for another set to do a similar thing. Now it is somewhat curious that a journal distinguished for its severe criticism of the medical profession, in lamenting the "rampant lawlessness" of modern unrest, makes no mention of the "doctors," who, of all others, have defied the tyranny of an Act of Parliament. The explanation apparently is that they have been too strong for the Government and that we are on the verge of a settlement that will practically concede the just demands of the profession.

Report of Select Committee on Nostrums. THE *Daily News*, the above-mentioned castigator of medical ethics, has published no report whatever of the past few sittings of the Select Committee of the House upon proprietary remedies. In place of it there are numerous advertisements of nostrums of all kinds claiming to cure a host of maladies, thus usurping a function which the State four centuries ago decreed in its wisdom should be entrusted solely to duly trained and licensed medical practitioners. The *Daily News*, however, is paid for publishing the claims of ignorant and unlicensed persons to cure all human maladies, whether curable or incurable. It is readily understandable, then, why that journal should decline to publish evidence exposing the real nature of such remedies, or to advertise the British Medical Asso-

ciation book detailing their analyses and scientific value. Assuming that a hundred pounds a day is received for the columns of advertisements of nostrums and unqualified methods of treatment in that journal, the yearly total accruing from that quarter accounts for a good deal. What need is there of a medical profession at all? The average man in the street has only to read the advertisements in the daily newspapers and choose his own medicines. Why waste his time and money in going to surgeons and consulting-rooms? Moreover, he has sound justice on his side, for it is he in the long run that pays the advertisement bills of the newspaper proprietors.

The Notification of Venereal Diseases. The prevalence of venereal disease in the United Kingdom constitutes a standing reproach to our modern methods of dealing with communicable disease. From a strictly logical point of view there is little consistency in saving or attempting to save folk, in spite of themselves, against such maladies as small-pox, scarlatina and enteric fever, if we leave a terrible disease like syphilis to stalk naked and unabashed throughout the Kingdom. The main difficulty in dealing with venereal disease arises from the question of sexual morality with which it is inseparably combined. When called upon to treat a patient suffering from pneumonia or quinsy we do not seek to learn his views upon monotheism or the Lord's Supper, or any other doctrinal matter; we simply cure or relieve him as quickly as may be. Yet the provision for the treatment of venereal diseases in the United Kingdom is scanty, perfunctory and furtive in its methods. The result is that many innocent persons are branded with the physical disabilities attached to these most preventable of diseases, and the State suffers from a constant drain upon the health of the community. Why cannot religious leaders face the position squarely and fairly?

LEADING ARTICLES.

THE INSURANCE ACT AND A PUBLIC MEDICAL SERVICE.

Now that the principles of practical organisation have been firmly grasped by the medical profession, there seems to be every prospect of speedy and satisfactory results. The whole history of the insurance negotiations with the Government, indeed, points to a continuous development of policy based upon lines of diplomatic diplomacy which would do credit to any political party in the state. The early days of the Bill were marked by an obvious attempt on the part of its framers to play fast and loose with the medical profession and to force upon them terms that were advantageous to the community at large, but disastrous to the last degree as regards the interests of the large class of private practitioners upon whom would fall the duty of administering medical benefits under the Act. The Chancellor of the Exchequer, in his anxiety to carry through a piece of difficult legislation at all costs, fell into the perhaps not unnatural error of imagining that in negotiating with the Council of the British Medical Association, he was dealing with the profession itself. From that dream he was rudely awakened by the clamour raised from one end to the other of the medical

profession upon his appointment of the medical secretary of the association, Mr. Smith Whitaker, to the chairmanship of the Insurance Commissioners. The day of that announcement witnessed the birth of medical organisation as a practical and living force. The Council of the Association, curiously enough, still holds the reins of government of the Association, in spite of a hailstorm of votes of censure from all parts of the Kingdom. The first great fruit of the new spirit, however, was to force upon the Government the six cardinal points as the serious ultimatum advanced by the profession. From that time there has been no wavering, and Mr. Lloyd George must have realised that there can be no alternative basis of agreement if the medical benefits of the Act are to be administered by duly qualified medical practitioners. At the present moment, nevertheless, we are within a few days of the launching of the Act, and so far no agreement has been arrived at. Yet the pamphlets issued wholesale by the Government dwell pointedly on the advantages of free medical advice and medicine which will accrue to the insured. Out of all this tangle emerges the solid fact that at the eleventh hour medical men do not know what will be the exact position offered to them under the Act. It has been wisely resolved, therefore, to be prepared for all emergencies by resolving, as a profession, not to take contract practice on any terms short of those demanded by the cardinal resolutions, and by organising forthwith an alternative public medical service, the management of which should be retained in the hands of the profession. In the latter connection an important step has been taken by the medical men of the borough of Leicester, Leicestershire and Rutland. They have resigned as a body all positions held in connection with friendly societies, clubs and dispensaries, the said resignation to take effect in December. Their official resignation is accompanied by a letter announcing the formation of a public medical service for the area concerned, the same to be absolutely under professional control. This straightforward action, we venture to hope, will commend itself to medical men generally throughout the Kingdom. There is no better safeguard of individual rights than a properly equipped organisation for effective defence. Had the profession simply maintained its ultimatum without establishing an alternative public service, it would simply have burnt its boats and been at the mercy of the enemy. Meanwhile it has been impossible to gain any definite information, in or out of Parliament, as to the exact position of the negotiations with regard to the co-operation of medical men under the Act.

THE HEALTH OF THE CITY OF LONDON. IN 1911.

THE annual report of the Medical Officer of Health for the City of London, Dr. W. Collingridge, has recently been issued, and, as might be

expected, contains a large amount of useful and interesting information. In the first place it should be borne in mind that there is, of necessity, a great difference between the day and night population of the City. The former was estimated by the census of 1911 as 364,061 persons, while the latter was only 19,475. It is upon the residential population, therefore, that all vital statistics in this report are calculated. On these figures the death-rate last year was only 10.9 per thousand of the population, as compared with 15.0 per thousand for the whole metropolis, rather a striking difference. The infantile mortality of children under one year of age was 46.3 per thousand, as against 128 for the whole of London. Such a low mortality is a great triumph for modern sanitary science, and is no small tribute to the zealous manner in which hygienic measures of every kind have been carried out by the health authorities. The compulsory notification of chicken-pox, cerebro-spinal meningitis, and pulmonary tuberculosis, has, of course, helped to diminish the risk of infection from these sources. It may not be generally known that arrangements have been made for the free examination of specimens for pathogenic bacteria sent by medical practitioners in cases of infectious disease occurring amongst their patients residing in the City. Dr. Collingridge calls attention to the fact that the number of conscientious objectors is still far too high, being 11.9 per cent. It is not pleasant to think what would happen in the event of an outbreak of small-pox in the City amongst so many unprotected persons. Some day, when it is too late, the legislature will wake up to find the metropolis in the throes of a fearful epidemic, and then, perhaps, after the population has been devastated, it may begin to consider the advisability of repealing the Vaccination Act of 1907. The work of the Woman Sanitary Inspector, retained by the Corporation specially to inspect and report upon conditions affecting infantile mortality, has borne excellent fruit. During the hot, dry weeks of last summer, May to September, only five deaths from diarrhoea or enteritis in infants were registered in the City. The investigation into the character of the milk arriving in London has received considerable attention, no less than forty-two samples having been taken at railway stations in the City on arrival from eight different counties, and submitted to Dr. Klein for bacteriological examination. Of these, twenty samples caused disease, either acute fatal results, or local inflammation and abscess, when injected into guinea-pigs, though none produced tuberculosis. The number of samples in which dirt was found is fairly large, and this indicates an unsatisfactory state of affairs, either at the farm or during transit. One of the most important portions of the report is that dealing with the supply and the inspection of meat and fish. The Corporation have now a laboratory well fitted up for all examinations of meat, with every necessary appliance. It is stated that out of the 435,316 tons of meat, fish and poultry dealt with

at Smithfield in 1911, only 22 tons 4 cwt. 2 qr. 6 lb. were found to be tuberculous. With regard to shellfish, Dr. Collingridge believes that the time has arrived when some legislative measure should be placed upon the Statute Book, prohibiting altogether the sale of oysters, winkles, cockles, etc., from any polluted source, for as long as the protection afforded to the consumers of meat and other foods is withheld from the consumer of shellfish, the consumption of these edibles must be attended with a certain amount of risk. It is satisfactory to note that offences under the Sale of Foods and Drugs Act showed an appreciable diminution as regards the percentage of cases of adulteration, as compared with previous years. Altogether, Dr. Collingridge is to be heartily congratulated upon the success of the past year's work, while the residents of the City of London may sleep soundly, well knowing that their sanitary interests could not be looked after better in any other city in the world.

CURRENT TOPICS.

The Medical Defence Union.

A STUDY of the annual report of the Medical Defence Union for 1911, which has just been issued, shows that the work of this indispensable protection society has been carried on with unabated vigour and with increased usefulness. The passing of the National Insurance Act, as might be expected, has caused hundreds of members to seek for advice upon numerous vexed questions in respect to their positions and practices, and it is proposed to appoint a Standing Committee especially to deal with these problems that must become more and more frequent as time goes on. A timely warning is contained in the report against the assistance given, sometimes unknowingly, by consultants, specialists, and other registered medical practitioners to unqualified persons who may assume styles and titles implying that they are entitled to practice medicine. The Union is ever upon the alert to prosecute such persons wherever this is possible, so that the position and interests of qualified practitioners are thereby supported and protected. A perusal of the solicitor's report shows the extensive nature of the legal defence conducted by the Union on behalf of the members. Of the 141 cases falling within the year's work, 45 had reference to libel and slander actions; 35 were associated with claims for damages for alleged malpraxis; 7 were directed towards the prosecution of unqualified practitioners and the suppression of unqualified practice, while the remaining 54 had to do with matters of personal and general import. The benefits that are derived from membership of the Medical Defence Union, the premier society of its kind, are so material and obvious that medical practitioners who are not thus protected should seriously reconsider their position. All medical men, whatever the nature of their practice, may be liable to actions for alleged negligence, or may be otherwise victimised, and it is much safer to be wise before the event. *Verb. sap. sat.*

Pollution of Swimming Baths.

WE are apt to regard the increased use of swimming baths both by school children and by adults as conducive to the better health of the community, and in the main we are right. Nevertheless, there are dangers which must not be overlooked. It has been suggested that outbreaks of poliomyelitis have been due in some instances to infection of public baths; but the matter yet awaits proof. That bath water may be highly infective, however, with the germs of disease has been proved by Dr. Graham Forbes. In a pamphlet on "The Pollution of Swimming Baths," recently published by the Medical Officers of Schools Association, he relates his investigations into the bacterial flora of a small swimming bath in an industrial school of the London County Council. He found that after the water had been in the bath for a few days he was able readily to separate such organisms as *Staphylococcus aureus*, *Streptococcus faecalis* and *Bacillus coli*. The latter was present in all but the smallest quantities of the water examined. There was thus distinct evidence of faecal contamination of the water. The presence of such organisms as have been mentioned is sufficient to explain outbreaks of such infections as conjunctivitis and sore throat. One can see, also, how readily typhoid fever might be disseminated from an infected bath. It therefore behoves all who have the care of baths used by a number of people to adopt stringent measures to secure the innocence of the water used. Either the water must be changed with greater frequency than is the custom at present, or measures must be adopted to secure its sterilisation.

The Opening of the King Edward Infirmary at Bristol.

A FURTHER evidence of the deep interest taken by King George V. in the welfare of the hospitals was given last week, when his Majesty visited the ancient city of Bristol to open the new King Edward VII. Memorial Infirmary. Realising the hopelessness of attempting to deal piecemeal with the old buildings, the governors recognised in Sir George White, their new president, a leader possessed of daring and initiative, and thus it is that the new building, estimated to cost £70,000, has now been opened. Accommodation is provided therein for 181 patients, and it is to be devoted to surgical, casualty and special departments. According to the War Office scheme, it is necessary to provide a base hospital in Bristol, with 520 beds. By the opening of the new infirmary and extension of the Nurses' Home 600 beds could be placed at the disposal of the military authorities, should the occasion ever arise, for the Royal Infirmary is the base hospital of the Second Southern Military District. We may join in the hope, expressed by his Majesty in replying to the address from the governing body, that the necessity for such a subsidy may never arise, but, at the same time, it is gratifying to realise that the spirit of patriotism is not antagonistic to that of providing for the relief of the sick and suffering on the most lavish and scientific scale. The arrangement and equipment of the new infirmary leave nothing to be desired, and the building is a standing monument to the large-heartedness of the citizens of Bristol.

The General Medical Council and the Maternity Benefit.

THE General Medical Council has, in a memorandum published a few days ago, drawn the attention of the National Health Insurance Joint Committee to the necessity of the regulations of the various commissions being so framed as not to permit the administration of the maternity benefit to interfere with the due training of medical students in practical midwifery. It is a subject on which we have commented more than once. There has been some difference of opinion as to whether the words of the Act allow of the framing of regulations sufficiently strong to safeguard obstetrical teaching. It has been assumed in some quarters that amendment of the Act would be necessary. The General Medical Council, acting presumably on counsel's opinion, does not take this view. The Council maintains that it is in the power of the Commissioners to make the regulations sufficiently clear and strong, and the memorandum puts the matter clearly before the Joint Committee. In a letter of acknowledgment, Sir Robert Morant states that he fully recognises the importance of the recommendations of the Council, and, when the time comes for framing regulations, will take into account all they have said. We hope that the action of the Council will make sure that the danger threatened by the maternity benefit may be avoided.

Pedestrians and Vehicles.

IN all civilised cities there are by-laws governing vehicular traffic. Not only is the driver of a vehicle subject to action for damages should he injure anyone by breach of the traffic regulations, but he is punishable by fine for mere breach of them, even without the infliction of any injury. In few places, however, are there regulations to govern the movements of pedestrians. It is, indeed, alleged by strangers to Paris that, should a foot-passenger be so unfortunate as to be run down by an automobile or a *fiacre*, it is he, and not the driver of the vehicle, who is liable to legal penalties. However this may be, there is no doubt that it is almost as necessary in a large city to control pedestrian as vehicular traffic. Every cyclist and motorist knows the foot passenger who steps suddenly off the footpath, or who wanders along the middle of the way, or who chooses to cross the street obliquely rather than by the established crossings. Such people are not only in constant danger themselves, but they constitute a danger to others. It is true that in the course of time a process of natural selection would probably eliminate them. In the meantime, it is not fair that they should be permitted to harass the more careful members of the community. It is satisfactory to find that the more progressive people of the West have not only invented an appropriate term for the class of whom we have spoken, "jay walkers," but have determined to regulate them as well as vehicular traffic. Kansas City, for instance, has adopted an ordinance for the control of pedestrians, and the experiment will be watched with interest by the rest of the world.

The Health of Europeans in West Africa.

IT is gratifying to note that, according to a White Paper recently issued by the Colonial Office,

the health of European officials resident on the West Coast of Africa shows a considerable improvement last year as compared with former periods. Thus, in 1911 the total death rate was 13.9 per 1,000, a decrease of 6.5 from that of the previous year; excluding five deaths due to causes other than disease, the rate per 1,000 was 11.7, or a decrease of 5.0 from the corresponding rate for 1910. The considerable fall in the death rate for 1911 must be regarded as very satisfactory, especially in view of the fact that during the year there were serious outbreaks of yellow fever in the Gold Coast and the Gambia. These outbreaks accounted for the deaths of 13 non-native officials in the two Colonies, in addition to the four deaths of officials included in the returns. The larger number of deaths were due to blackwater fever and yellow fever. Twenty-two deaths occurred in West Africa, eight in this country, and two at sea. A further decrease of 7.3 per 1,000 in the invaliding rate may be noted, but it should be stated that the number pensioned on account of ill-health has very nearly doubled, though the proportion of these to the total has not materially altered. It may be mentioned, as supporting the view that a man quickly recovers from the effects of the West African climate, that officials invalidated from the service are not infrequently found fit for re-employment after residence of a year or so in this country. Also officials, when pensioned off, generally enjoy their pensions for many years; in one or two cases the period on pension has been as much as 40 years. With the progress of sanitary science we may expect to see a still further diminution in the death rate among Europeans in this tropical region.

The Museum of the Royal College of Surgeons.

ONE of the most interesting places in London to the medical practitioner or student is the museum of the Royal College of Surgeons in Lincoln's Inn Fields. According to the annual report of the Museum Committee, recently issued, the collection has been enriched by the addition of over one thousand specimens. Priority of place must be given to a collection which has been presented by the executors of the late Lord Lister through the president of the college, Sir Rickman J. Godlee. This comprises Lord Lister's surgical instruments, appliances used in early researches, records, and tracings of experiments, drawings, and pathological specimens. Another collection of surgical instruments, formerly the property of the Obstetrical Society, was presented by the Royal Society of Medicine, while Mr. Penrose Williams, of Bridgewater, has presented the whole of his collection, containing many desirable specimens. The college has also acquired by purchase several crania and skeletons of the native Australian race, while several presentations have been made which are of real value. Many rare and valuable specimens have been added to the series illustrating the osteology and diseases of the ancient Egyptians. Remains of ancient man have also been presented which were found in a cave, with wall decorations of a primitive type, in the south of Spain, and some casts of certain remains of ancient man which have given rise to much discussion in Europe. These are the only casts so far received in England. The Archaeological Society of Broadstairs presented a series of skulls and skeletons belonging to the Bronze and Anglo-Saxon Periods. These have been investigated and, for the first time, an approximately complete articulated skeleton of one of the

Bronze Age man has been obtained. The medico-legal collection, recently formed, will prove to be a most interesting section, towards which a human femur, with photographs of human remains, found in the ruins after certain Anarchists were besieged in Sidney Street, Whitechapel, in January, 1911, has been presented. The specimens were the means by which it was established that one of the men who perished in the ruins was "Joseph"—a notorious Anarchist. These new additions to the museum will be on view on the occasion of the Council Election on July 4th, and also on the two following days.

PERSONAL.

T.M. THE KING AND QUEEN visited the Royal Hamdryad Seamen's Hospital at Cardiff last week, spending some time in the wards of the institution.

H.M. QUEEN AMELIA paid an informal visit to the London (Royal Free Hospital) School of Medicine for Women last week, being received by Mrs. Garrett Anderson, M.D., and conducted over the Medical School.

MR. ASLETT BALDWIN, F.R.C.S., has been appointed Surgeon to St. Mark's Hospital.

MR. G. F. DARWALL SMITH, M.B., B.Ch.Oxon., F.R.C.S., has been appointed Assistant Obstetric Physician to St. George's Hospital.

SIR THOMAS BARLOW, Bt., K.C.V.O., M.D., was among the recipients of the Hon. Degree of D.C.L. of the University of Durham last week.

DR. M. CAMERON BLAIR, of Northern Nigeria, has been elected President of the Caledonian Medical Society for next year, when the annual meeting will be held in London.

THE subject of the address of the President of the British Association, Dr. E. A. Schäfer, F.R.S., at this year's meeting at Dundee will be "The Nature, Origin and Maintenance of Life."

DR. E. E. GLYNN, M.A., M.D., M.R.C.S., L.R.C.P., has been appointed to the George Holt Professorship of Pathology at the University of Liverpool, rendered vacant by the death of Sir Rubert Boyce.

DR. T. STRAIN, M.O.H. for Barnes, has been appointed Medical Officer of Health for the Heston and Isleworth district, in succession to Dr. G. F. Buchan, who has been appointed to a similar position at Willesden.

DR. VICTOR JAMES WOOLLEY, M.D., of King's College, Cambridge, has been awarded the Raymond-Horton Prize for 1912 for his M.D. thesis upon "The Time-Relations of the Actions of Entero-Kinase and of Trypsin under Various Conditions."

THE thesis submitted by Dr. Alfred Ernest Barclay, B.C., M.D., of Christ's College, for the same degree, gained a *proxime accessit*, the subject being "The Diagnosis of Gastric and Œsophageal Affections by X-ray Methods."

MR. H. W. ARMIT, M.R.C.S., L.R.C.P., Secretary of the British Section of the International Hygiene Exhibition at Dresden, has received from the Royal Saxon Government, as a memento of their appreciation of his co-operation, an ornamental piece from the Royal Porcelain Factory of Meissen.

FRENCH CLINICAL LECTURE

ON

DECANCERISATION. (a)

By Dr. J. GAUBE DE GERS.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

By the word "decancerisation" I mean the disappearance under the influence of a special treatment of all cancerous manifestations in man. Biologic mineralogy has furnished us with the elements for curing cancer in man, as it has also furnished us with the elements of curing other grave diseases. It is thus that decancerisation is obtained by means of a colloid of copper introduced into the organism by subcutaneous injection.

What is cancer? We are ignorant of its essence; we know cancer by the nature of its qualities, by its manifestations, of which the most characteristic is an unlimited proliferation of a cellular element penetrating into the neighbouring tissues until they are destroyed and capable of infecting all parts of the body; hence it may be affirmed that every cancer whose proliferation is arrested is a cancer cured. Well, our colloid of copper rapidly arrests the proliferation of the cancerous cell. Is cancer contagious? Is cancer hereditary? In the present state of our knowledge, it is very difficult to answer affirmatively or negatively this question; however, it seems to me that there exists beyond all doubt a cancerous soil.

I have already collected a large number of observations of men and women affected with cancer. In nearly all I found a family aptitude to cancer. I know a family in which cancer has been perpetuated for the last two hundred years, either in the principal branch or in the collateral branches. Without doubt there exists in this family a soil specially prepared for the development of cancer. It is not rare to meet with persons predestined to cancer by the constitution of their soil, which, if particularly studied, will be found to contain a great abundance of chlorine and oxalic acid independently of the food régime; the soil of a confirmed cancerous patient is saturated with these minerals, but it varies according to the nature of the organs affected. On the other hand, the provoking causes of cancer are the same for all human beings. Cancer of the breast is one of the most frequent in women, yet every woman who has received a bruise on the breast does not present cancer. Smokers are much more numerous than epitheliomas of the tongue.

No matter what may be the nature and the heredity of cancer, I believe myself justified in stating that the cure of cancer is possible to-day, either in the case of non-operated cancer or in relapse after operation, provided that the lesion of the organs or the generalisation of the disease has not rendered all life impossible. Our colloid of copper is a colloid of protoxyde of hydrated copper; it is obtained chemically by reduction of salts of copper in presence of albumosic acid. Why did I choose copper instead of any other metal? First, because in my youth I learnt to consider the waters of St. Christav as efficacious against cancers of the tongue and the skin. The efficacy of the St. Christav waters was derived from the presence of copper in their constitution—at least, it was

thought so. I must confess I thought so also, and I think so still.

Secondly, because, in treating cancer, I never employed but those metals which enter as elements of constitution in any of the animal varieties, because I remarked that the elements thus chosen were but slightly toxic for man; copper is the predominating element of the mineral matter contained in the colouring matter of the blood of the octopus—the dreadful animal that everyone knows. The beneficial action of the waters of St. Christav on cancer brings to my mind a case of the highest interest possessing all the value of an experiment, and which was told me by a distinguished chemist. Some ten years ago M. J., manager of an institute for the culture of yeasts, sent one of his assistants to Paris to put up a plant. It was at the time when all kinds of yeasts or ferments began to be employed in therapeutics. It happened that the wife of one of the directors of the establishment, who was suffering from a tumour of the breast, took the yeast coming from the newly installed apparatus. This apparatus was in copper, and each time the lady took the yeast prepared in this apparatus she got relief from pain, and in time the volume of the tumour diminished in notable proportion. But, as the chemists had remarked that the yeast prepared in this apparatus contained a certain quantity of copper in its protoplasm, they erected alongside another apparatus made entirely of glass. From this moment the patient took the yeast from the glass apparatus, but, without knowing why, she experienced no longer any benefit. The colloid of protoxyde of copper was not prepared at first in a therapeutic point of view; it was prepared with other metallic colloids while seeking for the conditions under which the mineral matter is found in the different organisms. I prepared, preferably, colloids of biodynamic metals; copper, in general, is a biodynamic metal for certain species of animals—such as cephalopodes and crustacea. I remarked that those metals which are biodynamic for certain inferior animal species are scarcely toxic for man; on the other hand, we know that animal life is made up of a small number of metals only, so that the addition or subtraction of a biodynamic foreign element proper to the species modifies the mineralisation of this species, and with it the relation of the elements of constitution—in other words, its manner of life. In small doses, the antiseptic action of salts of copper is more than doubtful; in larger doses they are irritating; they coagulate albumen. On the other hand, the anti-cryptogamic action of salts of copper is proved for many years, principally when they have as adjuvants alkaline bases which provoke their reduction in a certain measure.

If the old adage: *Naturum morborum curationes ostendunt* were true, I should be right in supposing that the evolution of cancer in the human organism is produced by the presence of a cryptogam; but I know of no experimental fact up to the present which would corroborate the hypothesis. Colloid of copper should be preserved

in ampoules of yellow glass and free from light; the ampoules which we use contain five grammes (one drachm) and one hundred and one-hundredth of a milligramme (0.00121) of pure copper. The colloid is not toxic, and can be injected either under the skin or into the muscles. The injections are painless, but, on account of the viscosity of the liquid, they should be practised slowly. No reaction generally follows, either local or general; sometimes, when on withdrawing the needle a drop of blood is observed, a slight erythema may be observed the following day, but of no account. This insignificant accident may, however, be avoided by first inserting the needle, and if no blood comes out the injection may be practised. These injections are renewed every four days at the beginning of the treatment; afterwards they may be renewed less often and continued in the same conditions according to the susceptibility of the patient, or even repeated every two days, but never should the injection be made in the same place.

The reaction of the colloid on cancer is very manifest. From the first injections, the cancerous tumour, non-ulcerated, diminishes in volume, while the suffering becomes attenuated and the volume of the glands diminishes in proportion to that of the parent tumour; I observed in a number of cases that the glands became lenticular.

The curative action of the colloid would seem to be more slow on operated cancers and on relapses than on non-operated cancers. Every cancer abandoned to itself finishes by ulceration; under the influence of the colloid this ulcer decreases from the circumference to the centre as the cancerous tissue surrounding the ulcer disappears; the ulcer dries up in the centre, but it does not cicatrise before the peri-cancerous tissue disappears itself.

The secondary infections which so frequently accompany cancerous ulcer are but little influenced by the colloid, but I observed that from the *début* of the treatment of the ulcerated cancers, cases of secondary infections became more and more rare. The cancerous tumours are affected in a very special manner by the injections of the colloid of copper; they present to the touch no sign which would permit us to recognise the processes of regression or absorption; they present right at the moment of their disappearance the same sensation of sponginess or resistance, the same form. One sensation, however, remains, as much for the patient as for his friends, the disappearance of the tumour. This becomes so complete after a few months that it is impossible to find any trace of hitherto voluminous tumours. The cancerous cells are completely absorbed by the organism; I do not know the mechanism of the absorption, and have vainly sought for the products of this absorption in the humours and the excreta.

The intensity of the destructive action of the colloid of copper on non-ulcerated cancer appears to be in direct ratio to the rapidity of its development, that is to say, the colloid acts more quickly on cancers of rapid evolution, on acute cancers, so to speak, than on chronic cancer. I had a case of adenoma of the breast which remained torpid for several years; suddenly, from some unknown cause, it became painful and increased rapidly in volume. When I saw the patient, the tumour was irregular, hard, ligneous, and the volume of a large hen's egg; after three injections of colloid of copper, practised every eight days, the tumour diminished to the size of a small walnut; the pain had disappeared and the patient, who had not been able to lie on that side on account of the pain produced by the tumour, could change position at will. At the moment of writing these lines (February 12th), the patient is completely cured, no trace of tumour

can be felt; eight injections (one a week) sufficed to bring about a cure.

Do these injections produce a definite cure of cancer? Is decancerisation fully accomplished? For my part I have good reason to believe it, but my cases are too recent to be affirmative, they date from one, two, six and seven months. However, I observed three cases of cancer: one, a voluminous tumour of the left breast, another, a cancer of the larynx with a large gland on the right parotid, the third, a cancer of the stomach in the region of the pylorus; the two latter live a little outside Paris. After five injections, the third patient, for reasons not under his control, was obliged to interrupt the treatment. I saw him five weeks later and found that he was in the same condition as I left him, that is to say, the tumour was much diminished and painless, while the general condition had improved. I saw the second patient ten weeks after the third injection (the last) locally, the patient was in a satisfactory condition; the mass of glands of the neck had diminished, deglutition was improved as well as the voice, and so much that the patient ceased the treatment. The cancer of the breast, which was in a very satisfactory condition when the patient stopped the treatment, was found in the same condition six weeks afterwards. In these three patients, who only accepted the treatment for a limited time, if it was true that the cancer had not receded in a remarkable manner, yet the disease had not continued to develop and the characteristic pain of the cancerous evolution had not returned. It seems to me that the situation of these three patients, after several weeks without treatment, pleads in favour of the possibility of definite decancerisation, provided that the treatment be continued for a certain time after the complete cure.

I possess notes of fourteen cases of cancer treated by colloid of copper, of which four were completely cured, six are on the road to recovery, while the remaining four have been much improved. These fourteen cases comprise cancer of the breast; woman, 45, cured (father died of cancer of stomach, sister of cancer of the uterus); woman, 67, doing well; woman, 35, doing well (mother and two aunts died of cancer).

Left lobe of thyroid gland: woman, 72, doing well (father and grandfather died of cancer).

Epithelioma of the internal canthus of the left eye: woman, 56, cured; cancer of the caecal pouch, much improved (grandfather, grandmother and grand aunt died of cancer).

Voluminous sarcoma of the abdomen: man, 37, cured. Epithelioma of the cheek: man, 67, cured.

Cancer of the uterus beyond all chance of operation, much improved.

Cancer of the pylorus, woman, 63, much improved (mother and aunt died of cancer).

Cancer of the larynx: man, 56, doing well (father and grandmother died of cancer).

Cancer of the right fallopian tube: woman, 37, general condition deplorable, much improved (father died of cancer of the stomach).

I do not pretend to have given exhaustive clinical observations; I wanted simply to enumerate the cases of cancer I observed and to point out some of their most salient characters.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of this Journal. The lecture for next week will be by W. H. Willcox, M.D., F.R.C.P., Physician to Out-Patients, St. Mary's Hospital. Subject: "The Treatment of Dyspepsia."

ORIGINAL PAPERS.

THE PLACE OF X-RAYS IN
MODERN DIAGNOSTIC METHODS. (a)

By W. STEUART, M.R.C.S., M.I.E.E.,

Physician in charge of Electrical Department, Prince of Wales's Hospital, Tottenham.

OWING to the attitude adopted to X-rays in the teaching of clinical medicine and surgery, the general practitioner is not, as a rule, aware of the full diagnostic scope of the Roentgen ray. With a view to making students sound clinicians, they are taught to rely on the older methods, and if in answer to a question a student should happen to suggest X-rays being of use in a doubtful case, his reply is received with disdain. Now that your clinical methods and habits are firmly established, I can, without fear of corruption, indicate briefly how the X-rays may be of value as regards their more important applications.

Fractures and dislocations require no comment, but almost as characteristic and easily diagnosed as a fracture are other conditions of the osseous system. Chronic and acute inflammatory affections of bone can be readily recognised, and in the former case the appearance is usually suggestive of the exciting cause. Sarcomata not only disclose their nature on the skiagram, but it can be stated as to whether the growth is endosteal or periosteal. The type of an arthritis can generally be ascertained, as the variation in shadow caused by tubercle, osteo-arthritis, syphilis (Charcot) is distinctive.

By means of the bismuth meal and bismuth enema the whole course of the alimentary canal can be accurately examined, and the following conditions made out with complete certainty:—

Œsophageal obstruction.

Lack of tonicity of stomach and degree of hypotonicity.

Gastric ulcer.

Carcinoma of stomach or pylorus.

Pyloric obstruction and obstruction of small intestine and colon.

Viscerotoposis.

Bismuth has also been employed in mapping out the urinary bladder, and also for tracing the extent and direction of sinuses. Perhaps one of the most important diagnostic uses of X-rays is the detection of early pulmonary tuberculosis, and though this was pointed out more than ten years ago, and convincing proof brought forward again and again, this method even now does not receive its due recognition, but I venture to predict that X-rays, from the diagnostic standpoint only, will be one of the chief factors in the stamping out of pulmonary tuberculosis, and when this disease can be successfully dealt with other tuberculous lesions will become in consequence increasingly rare. As soon as physical signs become obvious the disease is in an advanced stage. The Victoria Park Hospital for diseases of the chest does not possess an X-ray installation, and usually some four or five cases each week of a doubtful nature are sent to us at St. Bartholomew's for examination. The majority of these are patients who have had hæmoptysis, but in whom no physical signs could be found. In such cases we have been able to detect the lesion, and, in addition, say how far the disease has advanced. In some instances the disease was so extensive that it was difficult to believe that physical signs could not be made out, but further clinical examination over the affected area rarely disclosed anything definite. The majority of these latter

cases were young people from 16 to 25 in whom the apices were entirely free, the disease affecting the area surrounding the peribronchial glands.

Effusion, whether pericardial or pleural, empyema, hæmothorax, pneumothorax, pyopneumothorax, aneurysm, hydatid cyst, mediastinal new growth, all give rise to different appearances which are so definite that little difficulty is experienced in coming to a diagnosis.

Urinary calculi cast shadows, the position of which indicate whether the stone is in the kidney, ureter or bladder. Difficulty is, however, experienced with uric acid calculi, as they are practically transparent to Roentgen rays and are easily overlooked. Pure uric acid calculi are not common, but at the same time the fact that no calculus can be demonstrated by X-rays is not absolute proof that it is not the cause of the patient's trouble. However, the skiagram so rarely fails, that unless the symptoms were very definite and urgent, surgeons would hesitate to operate without radiographic confirmation. Recently examinations have been made of the pelvis of the kidney and ureter by means of injections of collargol, the principle of the method corresponding to that of the bismuth meal.

Pituitary tumours which give rise to acromegalic symptoms can be made out, not so much by the shadow they cast as by the condition of the sella turcica and clinoid processes. Unfortunately, other cranial tumours, unless of bony origin, do not cast a shadow sufficiently differentiated from that of the main skull mass to enable one to give a certain opinion.

Pus in the antrum of Highmore, frontal sinus and ethmoid cells usually give rise to a shadow which can be easily distinguished. Patients are often sent up on account of obscure brachial paralysis of various kinds to ascertain the presence or otherwise of a cervical rib. Although most of these patients do not have a cervical rib, it is curious to note that many do have very long transverse processes of the seventh cervical vertebra, and when such transverse processes are so long that their tips extend as far out as the level of the articulation of the first rib with the transverse process of the first dorsal vertebra, then they often give rise to symptoms equivalent to those caused by a cervical rib.

Obstetrical and gynæcological work is still carried on without receiving much help from the radiological department, but it may be used to ascertain the relative diameters of the pelvis in difficult cases, and suspected ovarian tumours might be skiagraphed with advantage to exclude dermoids containing teeth.

I do not wish you to infer from the foregoing remarks that diagnosis in all the conditions mentioned is perfectly easy and straightforward, without the help of the history of the case, clinical signs and symptoms. But if the radiologist is provided with all the clinical data and asked to determine which of two alternatives is right, he will rarely fail to give a correct diagnosis.

A CASE OF INTUSSUSCEPTION IN
AN INFANT: RESECTION AND
RECOVERY.By H. F. WOOLFENDEN, M.D. LIVERPOOL;
F.R.C.S.ENG.

Honorary Assistant Surgeon, Liverpool Royal Infirmary.

RESECTION of the intestine in cases of irreducible intussusception is followed by such a high mortality, particularly in young infants, that a successful case in a child three months old is worthy of record.

(a) Abstract of a Post-Graduate Lecture given at the Prince of Wales's Hospital, Tottenham.

Makins (a) gives the statistics of all the cases at St. Thomas's Hospital from 1888 to 1908. Of the 27 cases in which the intussusception could not be reduced, there were only two cases which recovered, both being adults.

Clubbe (b) in 1905 records 100 cases of intussusception. In these resection was resorted to on seven occasions, with only one recovery.

Collinson (c) in 1907 reports a successful case in an infant three months old, which case shows points of resemblance to the following one.

J. D., a male, aged three months, was admitted to the Royal Infirmary on October 3rd, 1911. Prior to the present illness the patient had been a healthy baby. On October 2nd, at 12.30 p.m., the patient began to cry as if in violent pain, and he continued to whimper at intervals until admission. No fæces were passed from the onset of pain, but the mother noticed blood on the napkin. Next day she consulted Dr. Pendlebury, who sent the case to the Royal Infirmary for operation. On admission the temperature was 98° F., the pulse 160 per minute, and the child looked ill. The abdomen was tense, and any attempt to palpate the tumour caused the patient to cry. The napkin was blood-stained, and on rectal examination the apex of the intussusception was felt $1\frac{1}{2}$ inches from the anus.

Operation was performed immediately, 27 hours having elapsed from the onset of the condition.

Chloroform was administered; the abdomen was opened in the middle line below the umbilicus, the incision being subsequently enlarged upwards to just above it. The intestines were very markedly distended, and could not be kept inside the abdomen. After allowing them to prolapse, the intussusception, which was of the ileo-cæcal type, was easily reduced until it was in the position of the ascending colon; beyond this it could not be reduced, and on attempting to do so the outer layer began to split.

The unreduced portion was deeply congested, and a rapid resection was decided on.

The gut was doubly clamped above and below the mass; it was then divided, the vessels ligatured, and the mass removed. Two Paul's tubes were tied in the cut ends, no attempt being made to unite the ends. Before the distended small intestines could be returned into the peritoneal cavity, a considerable portion of their contents had to be emptied. The ends of the gut were fixed in the upper part of the abdominal incision, and the rest of the wound closed with through-and-through sutures.

After the operation the condition of the child was much more favourable than the severity of the operation had led one to expect. It was able to take its bottle a few hours later. The pulse, however, continued at about 160 per minute for the three days following.

On October 16th a pair of tongue forceps with narrow blades were passed up the open ends of the bowel and loosely clamped, the area of compression being about 2 inches above the opening. The forceps were tightened each day, and were loose in a week. From this time the bowels were moved naturally, and the fæcal discharge from the enterostomy was only slight.

On October 27th the child was anæsthetised, the enterostomy closed by turning in the ends of the gut and suturing the skin and abdominal muscles over them. It reopened, however, and a second attempt was made on November 7th. This was successful except at one point, where a small

fistula developed; this closed spontaneously in about 14 days.

The patient was discharged on December 5th with the wound quite healed. On discharge he looked in very good condition, being quite fat and well developed.

On examining the specimen after the operation, the intussusception was of the ileo-cæcal type; six inches of large intestine were found to have been removed; no gangrene was present, and apparently the irreducibility was due to the œdema present.

In view of this it is possible that if the attempts at reduction had been persisted in longer they might have succeeded; but it was impossible to say at the operation that there was no gangrene, and, moreover, the tear in the wall must have become complete.

No attempt to unite the two ends was made at the operation, for two reasons: first, the condition of the patient; and, second, it appeared that the only chance of recovery lay in the intestines emptying themselves freely, in order to relieve the marked distension present and to get rid of their toxic contents.

In the subsequent course a surprising feature was the little weight lost while the enterostomy was open. Another point of note was that the bowels moved naturally as soon as the clamp had made the lateral anastomosis. This apparently was due to the pouting of the mucous membrane at the enterostomy causing sufficient obstruction to make the contents of the small intestine pass through the anastomosis into the large intestine.

THE INGLEBY LECTURE

ON

PUERPERAL FEVER. (a)

By J. FURNEAUX JORDAN, B.Ch., F.R.C.S.,
Surgeon to the Birmingham Hospital for Women, and the
Maternity Hospital.

AFTER a few introductory remarks on the foundation of the "Ingleby Lectureship" in 1876, the lecturer said he had chosen the subject of Puerperal Fever because he felt that it was one of interest not only to obstetricians and gynaecologists, but even more to the men who are actually practising midwifery everywhere.

At first sight it might be thought that there was little or nothing even that was new to be said about puerperal fever. Every doctor knows the necessity of absolute surgical cleanliness when attending a confinement or miscarriage; every doctor knows that this cleanliness must also be extended beyond himself to the nurse, the patient, and any instruments or dressings, etc., that may be used; every doctor knows that the more thoroughly and completely this surgical cleanliness, this asepsis, is carried out, the less puerperal fever will there be amongst his patients; but every doctor knows also that however aseptic he is, whatever care he takes, some degree of infection or fever will occasionally occur.

There is no need for me to review before you all the predecessors to whose experience and teaching we owe the knowledge that we have to-day. It is quite certain that medical men never forget that whatever success they may attain to in medicine, or surgery, or midwifery, they owe for it a deep debt of gratitude to those who have gone before them.

In connection with the subject of the lecture to-day three names only do I mention—names that will occur to all of you—Pasteur, Lister, and the American physician whom most of us have learnt to love as the Poet, or the Autocrat, or the Professor.

At such a standard of uniformity, I may say of unanimity, has the teaching of puerperal fever arrived that the general public, with that avidity for which it is famous for absorbing anything which

(c) Collinson, *Lancet*, 1907, p. 1087.

(a) Delivered at the Birmingham University on May 23rd, 1912.

concerns its physical well being, now prides itself on knowing all about it.

When the medical practitioner comes downstairs, as he occasionally has to do, to tell the husband that his wife has got puerperal fever, how often is he met, if not immediately, certainly in a day or two, by the accusing question, "How did she get it? She must have got it from something or somebody"? How often, it is only fair to add, does the doctor himself say, "No one touched her but myself, I did everything I could to preserve asepsis, but I suppose something went wrong." To this question of responsibility, or not, we shall return later on.

It is impossible this afternoon to cover the whole of the subject of puerperal fever. I propose therefore to refer to the incidence of the disease, to some of its types which are fairly distinct, to the cause or causes as far as we know them, to some of the pathological changes, and the treatment preventive and curative.

Up till quite recently there has been great difficulty here in the way of making any study of these cases, because there has been little or no institutional treatment for them. They were, and are, certainly not wanted at the Maternity Hospital. No operating surgeon has ever been anxious to mix these cases with his operation cases, but some time ago now the Women's Hospital at Sparkhill had a ward specially built for the reception of septic cases, and into this we are able to take cases of puerperal fever. We also have an arrangement with the Health Committee of the City Council by which those cases of puerperal fever reported to the Medical Officer of Health which are unable to get any proper attention at home are sent in by him to the Women's Hospital. Into this ward last year 36 cases of puerperal fever were admitted. Cases of some septic condition or other, e.g., a parametritis or a pyosalpinx, ultimately following on and due to the confinement are not included in these 36. These are cases of puerperal fever coming on within a few days of the confinement. In the first three months of this year another nine cases have been admitted; of these 45 cases 15 have died, six of the 15 within three days after admission, six on days between the 7th and 14th after admission, and three on the 45th, 50th, and 55th day respectively. Even a preliminary examination of the cases shows that the first six were cases far too far gone at the time of admission for any treatment to have a chance of success; the second six were severe cases in which treatment was tried with very little effect; while the three who survived for so long were at death's door many times before they finally succumbed.

I propose to-day to dwell for a short time upon three types of case:—

- (1) Those that are of a mild type and recover easily.
- (2) Those that are acutely infected and die quickly.
- (3) Those that are severely infected or ill for a long time, and usually but not always recover.

In considering the first class, the less severely infected or the mild type, the most noticeable feature about them is that the temperature fell to normal in all but one of them within 48 hours after admission; in the one exception the fall was a gradual one, reaching normal on the 4th day. This is really a curious fact when one considers the following information about them. There were 10 cases of this type; we will call the day of confinement in all of them the first day:—

1.	Fever started on 7th day, admd. to hosp.	11th day with a temp. of	99.6
2.	" " 3rd " " "	21st " " "	102.6
3.	" " 5th " " "	7th " " "	101.0
4.	" " 2nd " " "	7th " " "	100.8
5.	" " 2nd " " "	4th " " "	100.0
6.	" " 3rd " " "	12th " " "	100.6
7.	" " 12th " " "	17th " " "	99.8
8.	" " 3rd " " "	7th " " "	103.8
9.	" " 12th " " "	19th " " "	103.8
10.	" " 3rd " " "	10th " " "	99.5

The duration of the fever, therefore, extended from two to 18 days before admission, yet after admission the temperature fell to normal in all of them in practically the same time, namely, about two days. It looks as though in each case the temperature was only waiting for treatment to come down to normal. The symptoms on admission were usually the rise of

temperature that I have already mentioned, quickening of the pulse to 100 or up to 120, but not higher; furred tongue; uterus big and tender; lochia usually profuse and foul smelling; constipation; and a general appearance of being ill. Three of the patients had a blunt curetting done the morning after admission, in two of the three some septic retained placenta was found, in the third case the uterus was clean. On admission to hospital the change from a poor, dirty little house, from inefficient attendance, from improper feeding, and in some cases from actual neglect, to a comfortable, warm, clean bed, and to good nursing and feeding, the change from the constant worry and anxiety at home to the general sense of well being and comfort in the hospital, the change from constipation to a thorough evacuation of the bowels, the change from dirt to absolute cleanliness, helped usually by a gentle antiseptic vaginal douche, and a tonic such as the *mist. ferri* seems to have been sufficient for a rapid recovery in these cases. We can only assume that the infection is slight, in some cases purely local, and that the resisting powers of the patient only want a little help to bring about a recovery.

I shall deal later on more fully with the actual cause of puerperal fever, but you will let me refer here briefly to the question of infection. The bacteriological definition of infection is the access of living virulent pathogenic bacteria to a region whence their toxins may act on the tissues of the body. It is well known to all of you that when infection occurs, recovery depends on the degree of immunity possessed or acquired by the patient. In these mild cases we simply help in the development of such a degree of resistance as will make them not only immune to further infection, but will enable them to sterilise or destroy the infection already present.

We now come to the second type of case—the acutely infected that die quickly. Early onset of the symptoms, a rise of temperature to 103 or 4 or 5, profuse sweats, a pulse of 120, and rising as high as 160, are sufficient to cause grave anxiety. In some of these cases the patient, however, looks fairly well, and except for feeling hot she may be quite comfortable, the pulse has a good volume, the bowels may be acting (but this usually only from treatment), the abdomen is slightly distended but quite soft, palpable, and free from tenderness, there is no uterine tenderness, there is nothing abnormal to be felt in the pelvis, and one may be inclined to give a hopeful prognosis. In reality the prognosis is very grave; the pulse gets weaker and weaker, the tongue becomes furred, and dry sordes appear on the lips and gums, the nourishment taken becomes less and less, rigors may or may not occur, prostration becomes more marked, the distension of the abdomen increases, constipation gives way to septic diarrhoea with involuntary evacuation, and the patient rapidly sinks from acute toxin poisoning. The rapidly fatal cases at Sparkhill were all in the latest stages of acute infection on admission, and it was impossible to render them immune to the infection; but that these cases are not necessarily fatal, and that they are not naturally bound to follow the distressing course I have briefly outlined, is known to all of you, and is well illustrated by three cases I have seen recently outside the hospital. The history of these cases is as follows:—

(1) Mrs. F., patient of Dr. Middleton. Confined on November 28th last, normal confinement, baby weighed 6 lbs. 13 ounces. Temperature rose to 103 on the 3rd day, the uterus was washed out with an antiseptic douche, a turpentine enema was given, and the temperature fell to 101. Vaginal douches were subsequently given, the bowels were kept open and tonics were administered. The patient felt better, and for four days the temperature hovered between 99.6 and 101.5. On the 8th day she had a rigor, the temperature rose to 105, and she felt very ill. I saw her with Dr. Middleton, and under an anæsthetic I took two swabs from the interior of the uterus for subsequent bacterial investigation, and also by exploration satisfied myself that the interior of the uterus was empty from any placental remains. After the rigor the temperature fell the next two days to normal, only

to rise on the third day after the rigor to 103. In the meantime Dr. Mackey had examined the swabs, and reported a profuse and practically pure infection of streptococcus. Of the vaccine he prepared from this 5 minims (containing nearly 30 million streptococci) were injected; in 24 hours her temperature came down to normal and never rose again. A second injection of 35 million was given four days later.

(2) Mrs. H., patient of Dr. L'Estrange Burges. Normal confinement on February 29th last, the temperature normal, and patient going on well till the seventh day, when her temperature rose to 104. I saw her with Dr. Burges, and carried out the same procedure as in No. 1, but in addition injected her with 4 minims of the stock vaccine of No. 1—that is, with 25 million streptococci; her temperature fell to 101 in the next four hours, but hovered between 101 and 102 for the next two days and then rose to 103, when she had an injection of 25 millions streptococci in 5 minims of her own vaccine prepared by Dr. Mackey from the swabs I had taken. Her temperature came down again to 101 for two days, and then rose to 104, when she had 50 million of streptococci in 8 minims of her own vaccine injected. In less than 24 hours her temperature fell from 104 to normal, and never rose again.

(3) Mrs. F., patient of Dr. Cochrane's, of Bloomsbury; second child; normal confinement. Three days later temperature rose to 104.2 with pulse of 144. When I saw her she presented the usual signs of an acute infection in the early stages. Since the patient was hardly able to afford the preparation of her own vaccine, a stock vaccine of the streptococcus prepared by Dr. Mackey from a previous case was used—25, 30 and 35 million streptococci being injected every third day. After the second injection her temperature came down, and never again gave any cause for anxiety.

Now these cases when first seen, especially No. 2, resembled in every way the cases which at a later stage have been admitted to Sparkhill only to die in a very short time.

I would note here that in these private cases treatment by vaccines, etc., was begun early in the disease, whereas in the six cases at Sparkhill that died within two or three days of admission they were only admitted to the hospital on the 3rd, 4th, 4th, 10th, 6th and 5th days respectively of their illness. In addition to the vaccine treatment in the three cases outlined, attention was paid to the bowels, suitable diet was administered, tonics given, and all of them had the benefit of good nursing. It is, of course, impossible to say for certain that with the ordinary measures of treatment, and without the vaccine, they would have developed the later symptoms such as those of the rapidly fatal cases at Sparkhill, but one cannot overlook the fact that in each of them a rapid and permanent recovery from a very serious condition followed this treatment. Before we leave these acutely infected cases, we must refer here briefly to the pathological changes found in them on post-mortem examination, and we shall derive most instruction from these if we take three or four cases in detail:—

(1) Mrs. L., æt. 28; five previous pregnancies; no miscarriages. Admitted to Sparkhill on May 5th of last year with a temperature of 105, pulse 130. Delivered eleven days previously by a midwife. Two days after delivery she had an attack of acute abdominal pain for which the doctor was sent for, vaginal douches were given and medicine. On the next day she had three rigors. The pain and the rigors continued until her admission to the hospital on the 12th day, when she was acutely septic and very ill, a most offensive vaginal discharge, no definite abdominal symptoms. On May 7th, two days after admission, Dr. Edge took swabs from her uterus and did a blunt curetting. On the next day her temperature was 101.6 in the morning, but in the evening she had a rigor and her temperature rose to 105.6; she had an injection of stock vaccine (25 million streptococci) and her temperature fell to 103 till the next evening when it rose again to 105. A second injection of stock vaccine was given, this time 30 million streptococci; her temperature came down for a few hours to

100, but rose on the next evening to 105.4, when she died. Dr. Mackey's report on the swabs showed an infection of streptococcus and bacillus coli. A mixed vaccine was prepared, but as the patient was near the end when it was ready it was never injected.

Post-mortem.—Body emaciated, no general peritonitis but some purulent fluid in the pelvis; uterus large and flabby, like an empty bladder, and containing some old blood clot, but not offensive nor obviously septic; the fallopian tubes contained pus, the left one being quite distended and the pus escaping from the fimbriated end when the tube was handled; no thrombosis in the pelvic veins; kidneys large and pale; spleen large, about ten ounces; liver honeycombed with gas bladders and the wall of the intestine emphysematous in parts, evidently from a gas-producing bacillus; lungs œdematous; heart extremely flabby, no endocarditis.

Mrs. H., admitted to the Women's Hospital under Dr. Martin on February 19th. Delivered eight days previously by a midwife who examined the patient several times before delivery. Placenta expelled without any difficulty. On the second day the patient felt very ill and feverish, having a rigor which lasted a long time, and two days later a doctor was called in who curetted her. She, however, continued feverish and shivering until the eighth day, when she was admitted with a temperature of 104.8, pulse 140, tongue dry and furred, abdomen tender and distended, uterus tender and somewhat fixed by a tender swelling to the right of the cervix. The interior of the uterus was bluntly curetted without an anæsthetic and swabbed with pure carbolic, and left with an iodoform gauze drain. Swabs of the uterus were taken before she was curetted, and report showed infection by streptococcus, but a streptococcus not the same as that found in other puerperal cases. A vaccine was prepared, but the patient died before it was ready for injection, her temperature rising the day after admission to 105.4 when she died.

Post-mortem.—General peritonitis, some purulent fluid in the pelvis and fibrino-purulent adhesions everywhere; uterus flabby, very friable, contents green and dirty with blood clots and (?) placenta; the broad ligaments infiltrated, and on cross section honeycombed with pus; the fallopian tubes, though not much dilated, contain thick yellow pus; the kidneys are congested, their pelvis dilated and they look moderately fatty; liver large and fatty degeneration; spleen large and soft; lungs congested; heart dilated, no endocarditis.

(3) Mrs. E., æt. 22; married 16 months; confined on December 18th, normal confinement. On Christmas Day acute pain in the abdomen, and on the next day diarrhœa and sickness, which persisted profusely for 24 hours. When seen by Mr. Hewetson, on December 27th, was very ill and acutely septic with a pulse of 140; she was given a morphia suppository which stopped the diarrhœa, and was admitted to the Women's Hospital on December 29th. Great pain in the abdomen, chiefly just below the costal margins when taking a deep breath; the sickness was better, there was albuminuria but no pus in the urine, was very emaciated, suffering countenance, tongue dry in the middle, heart and lungs normal, some distension of the abdomen with general tenderness, uterus tender but fairly well involuted. She had two enemata on the night after admission with fair results. In spite of treatment she gradually got worse, and died on January 3rd.

Post mortem.—Body pale and thin. Abdomen: general fibrino-purulent peritonitis from the pelvis to the diaphragm; uterus empty and not obviously septic, nothing wrong with the tubes, no purulent pelvic cellulitis; kidneys fair; liver large, and fatty degeneration well marked. Thorax: Pericardium contains 6 or 8 ounces of thick pus; heart flabby but no endocarditis; a recent pleurisy over the left lung, which is collapsed, no effusion and no abscesses in the lung, right lung adherent in several places, no abscesses, no pleural effusion.

(4) Mrs. S., æt. 26, fourth confinement on September 3rd last year, normal, attended by a midwife. On the second day after confinement had a rigor, became rapidly ill, and was seen by a dispensary doctor on

September 7th. I saw her with him on the same day. I found her in the midst of the filthiest and most poverty-stricken surroundings, and lying covered where the skin was exposed by myriads of flies, of which she took not the slightest notice: pulse 148, temperature 104; abdomen distended and tender in the lower part; uterus and broad ligaments very tender; respiration hurried and very difficult. I admitted her to the Women's Hospital at once. She never recovered complete consciousness; her temperature varied from 103 to 105.8, septic diarrhoea supervened, with rapid prostration and death five days after admission.

Post mortem.—Abdomen contained a few ounces of fluid but no pus; intestines and stomach were much distended with gas; uterus pale, rather large and soft, its cavity empty and not very septic looking; in the wall of the uterus there were one or two small abscesses; from the left broad ligament pus was obtained by squeezing, and the left tube contained some semi-purulent fluid; the pelvic veins were not thrombosed; the spleen was large and septic; liver large, very soft, and fatty degeneration, but no abscesses were seen; the kidneys were pale, large; cortex swollen and very fatty; kidneys typical of septicaemia. Thorax: In both pleural cavities there were some ounces of semi-purulent fluid; both lungs showed purulent lymph on their exterior, and both on section showed well-marked oedema and septic pneumonia; the substance of the lungs was very friable, and in both there were numerous small abscesses; the pericardium contained a slight excess of semi-purulent fluid, and there was early pericarditis noticeable on right auricular appendix; the heart muscle was pale and fatty, and the cavity showed a large amount of septic-looking clot; the mitral valves showed a few recent small vegetations, and the aorta some aortitis of the aortic sinus.

Reference has already been made to those cases that, although acutely infected and very ill, were in hospital for a long time and ended usually in recovery. If the histories of these cases are not becoming wearisome to you I would like, as briefly as possible, to record some of these.

(1) Mrs. H., æt. 27. Admitted to hospital November 15th, baby born on November 9th. Examined once before the membranes ruptured by the nurse attending her, but at the actual birth of the baby no one was present except a neighbour. Dr. Sangster was called in to remove the placenta. Followed later by profuse hæmorrhage, had a rigor same day, but after this felt well until the third day. On the first day she and her bedclothes were wet through by the rain coming in through the roof. On the third day began to feel hot, and her temperature remained high until she was sent to the Women's Hospital on November 15th with a temperature of 105, pulse 144. On admission abdomen slightly distended, no tenderness, uterus above the brim, profuse septic discharge, tongue furred, patient very anæmic. Next day, on the 16th, the temperature came down to 103 and her pulse to 118; blunt curetting was done and some small fragments of membrane got away. Before the curetting was done, two sterile swabs were taken of the uterine discharge from which to grow cultures; these cultures showed streptococci and bacillus coli. The temperature did not fall until the third day, when it came down to 101.4. On the evening of the third day she had an injection of her own vaccine, 4 minims. On the fourth day temperature came down to 100.2, but on the fifth, sixth and seventh days rose again to 102, 104 and 103. On the seventh day she had another injection of vaccine, 5 minims. Between then and the 13th day her temperature was down in the morning to 99.2 and twice to normal, but up in the evening to 102, and on the twelfth day to 103. On the thirteenth day another injection of vaccine, 6 minims, was given, after which her temperature hovered above normal day after day for a fortnight. She had two more injections of vaccine, 8 and 9 minims respectively. The next week the temperature was higher in the evening than the previous fortnight, though down to

normal in the mornings, and it continued very much in this condition until the forty-ninth day. During all this time the patient complained of pain in the wrist, pain in the legs, and especially in the left ankle; the joints were swollen slightly, acutely tender, but as time went on both the swelling and the tenderness gradually disappeared except in the left ankle, where a swelling persisted and the tenderness remained acute. Repeated examination of the chest, of the abdomen, and the pelvis failed to elicit any cause for her temperature, the serous effusion round the ankle joint not being sufficient to account for such an irregular temperature. On the fiftieth day a slight tenderness and swelling was noticed over the back of the sacrum, and on the next day the swelling had increased considerably. An incision was made into it and a large quantity of pus let out. Her temperature fell the next day to normal. Her recovery from this time onwards, though very slow, was steady. Massage to the left leg and ankle helped her to gradually recover the use of the leg, and for a week before she was discharged to the Convalescent Home she was able, with some assistance, to put her foot to the ground and to hobble about.

This, with the case of Mrs. D., the third case I shall describe, are both examples of infection in which quite late in the course of the disease a local abscess forms, the opening of which seems to put an end to the invasion of the tissues by the germs, and to allow of the immunity which they gradually acquire to take effect.

(2) Mrs. T., æt. 28. Delivered at her home on October 31st at 10 a.m. Fifth pregnancy. The nurse arrived 8.30, membranes ruptured 9.15, some difficulty in delivery from the size of the head and shoulders. Baby was asphyxiated, and while it was being attended to the placenta was expelled—not intact. After the third stage rather more than the normal loss. On November 2nd temperature was 101 and pulse 120 when the nurse visited her; the bowels had not been moved, and an enema was given. On November 3rd temperature still up, and admitted to Sparkhill at 7 p.m. with a temperature of 102.6, pulse 132. Two intra-uterine swabs were taken and sent to Dr. Mackey. Cultures showed streptococci, and a vaccine was prepared. For two days after admission her temperature came down to nearly normal, but a smelly, purulent, bloody discharge persisted; so on the fourth day after admission a blunt curetting was done, and a largish piece of septic placenta was removed; her temperature rose to 102.5 on the same evening. The next morning she had an injection of vaccine, 2 minims; that was on the second morning. Temperature kept up till the fourth morning, when it began to fall, and fell in 24 hours to normal, and kept so for two days. Sixth day, injection of vaccine, 3 minims. On the seventh day temperature rose to 101, and remained irregular, up and down, until the thirteenth day. On the tenth day, up to which she had looked and felt well, she complained of pain in the left side of the chest. On examination of her chest I could find slight impairment of the breath sounds at both bases and diminished movement of the left side of the chest. Pain passed off, and patient seemed well till the twenty-first day, when complained again of pain in the left side in the lower axillary region and in the left shoulder, especially marked at end of inspiration. On the twenty-first day—i.e., November 27th—she was examined by Dr. Mackey. Movement of left chest much diminished, resonance impaired in front and duller still behind, especially at the base, where the breath sounds were very weak, but breathing not bronchial, though expiration heard better than inspiration. Vocal resonance resembled ægophony, and there was whispering pectoriloquy. No pleural friction heard, right side normal. On November 28th, or twenty-second day, 6 minims of vaccine, but her temperature remained irregular, between 99.5 and 102. On December 3rd the dullness being more marked and increasing, the chest was aspirated; no fluid found. On December 7th aspirated again and found fluid and drew off two

pints of straw-coloured, slightly thickened fluid, after which, from the 6th to the 16th, her temperature was still up at night and down in the morning, varying from normal to 100 and 100.5. The aspirator was used again on the 16th, and between three and four ounces more fluid were drawn off. The fluid contained chains of streptococci similar to those of the uterus. Injections of vaccine on December 2nd, December 7th, December 12th, and December 19th were given, increasing the dose by 1 minim each time, but with no effect on the temperature until after the second aspiration, after which her temperature rose twice on 18th and 19th to over 100, but afterwards remained normal till December 31st, when she went home feeling quite well, and has remained so. On December 30th Dr. Mackey reported left chest somewhat dull, air entry poor, but breath sounds better heard than formerly and vocal resonance fairly good. Aspiration in two places, no fluid. Patient all along looked fairly well in spite of her high temperature and quick pulse and effusion into the pleura.

(3) Mrs. D., æt. 31, eighth pregnancy. Admitted January 21, 1912, to the Maternity Hospital and confined in the evening of the same day. Before admission to the Maternity Hospital she was examined by a midwife and by a doctor. Presentation transverse. On the 20th, at 1 p.m., the membranes ruptured but no pain; at 11 p.m. a limb presented, and the doctor who was called in sent her to the hospital. She was admitted at 4 a.m. on the 21st. Examination on admission showed an arm presenting, there were no pains, and at 6 o'clock in the morning Dr. Potts did internal version by bringing down a leg. The patient had no more pain till 5 p.m., when sharp rapid pains came on and the baby was quickly born; placenta delivered in half an hour (manually). An intra-uterine douche was given. At the end of labour the pulse was 86. There was no tear of the perineum.

January 22nd. Pulse 96, temperature 100.5. Patient complained of pain in the right wrist. Vaginal douche twice a day.

On the next day the temperature was higher—over 101.

The next day it went up to 103, and she complained of great pain in the right wrist and both legs. No swelling of the joints, which appeared freely movable. Very wheezy in the chest, harsh breath sounds all over the lungs. Lochia offensive and scanty.

The next day temperature 102. An intra-uterine douche was given, cultures taken from the uterus, and Dr. Thomas Wilson curetted her. A great deal of clot and *débris* came away. The same night 20 c.c. polyvalent anti-streptococcic serum given in the abdominal wall.

The next day patient seemed a little better, but still the pain in the wrist and the legs. The gauze packing of the curetting was removed and a douche given.

Cultures grown showed streptococci.

Two days later, on January 26th, temperature still up to 102, lochia still offensive, two rigors in the morning, uterus flushed with 5 per cent. hydrogen peroxide.

January 27th.—Much the same, cough more troublesome, at left base behind the percussion note is impaired, few crepitations and a pleuritic rub can be heard sometimes.

January 28th.—Condition the same, abdomen rather distended but no tenderness, uterine discharge clear, sputum shows pneumococcus. Patient had two rigors yesterday.

January 29th.—Much the same.

January 30th.—Patient still holding her own, moist crepitations, pleural friction over the left base. Slight rigor this morning.

January 31st.—Patient's aspect not so good, pulse becoming more rapid, abdominal distension increasing.

February 1st.—Still a good deal of distension, tenderness in the pelvis, sputum bloodstained, and a tender spot over the left buttock.

February 4th.—Patient had a rigor yesterday afternoon; temperature 104.8, still feeling the effect of it to-day.

February 5th.—Condition much the same, left base

still dull, breath sounds deficient, abdomen not tender and the spot on the left buttock less so.

February 6th.—An abscess in the left buttock was opened and four ounces of thick pus let out. Cultures of pus showed streptococci and bacillus coli. Left base still dull.

Patient continued about the same, and examination on February 12th showed that the uterus was involuted and no hardness or tenderness in either fornix, breath sounds rather deficient in the left base, nothing else abnormal.

During the next week she had several rigors, and on February 19th she complained of pains in the right leg below the knee, leg tender to the touch and looking larger than the other.

February 23rd.—Leg rather better, otherwise much the same. All this time her temperature was going up and down between 103 and normal.

February 27th.—Patient was given Burney Yeo's inhaler with creosote inhalation.

February 28th.—Half a grain collargol injected into basilic vein; left base behind still dull, breath sounds deficient.

February 29th.—Condition much improved, temperature having been practically below 100 for three days.

From now till her discharge a month later, on March 28th, the collargol was systematically administered. The patient progressed almost imperceptibly at first, but afterwards steadily and rapidly, and when she left to go to the Convalescent Home she was able to walk, and the wound in the back had quite healed.

(To be concluded in our next.)

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

WIRING FRACTURED PATELLA.—MR. WILLMOTT EVANS operated on a man, æt. 45, who had been admitted suffering from a fractured patella. The patient had fallen and struck his knee against an iron plate, and had then been unable to rise. On admission there was an obvious fracture of the left patella, a space of about an inch intervening between the two fragments. The fracture was transverse and the knee-joint swollen. The patient was kept in bed for a week, the limb being placed on a back splint. The operation was performed on the ninth day after the injury. The patient was anaesthetised with ether, and the operation area painted with a 2 per cent. solution of iodine. Then a horse-shoe incision was made with the convexity upwards, starting at one side opposite the tuberosity of the tibia, and passing upwards and across the limb at a point about an inch above the upper border of the patella, and then downwards to a corresponding point on the opposite side. The flap thus marked out was turned downwards and the fractured bone exposed. The two fragments were found widely separated, and there was much blood clot and serous effusion in the joint. The clot was removed with the finger, then the overhanging torn aponeurosis was cut away with scissors. A hole was next bored with an awl through each fragment, passing from the anterior surface about half an inch from the edge of the fracture to about the centre of the fractured surface. A piece of silver wire was then passed through the opening from one fragment to the other, and by traction the two fragments were thrown into apposition. The ends of the wire were then twisted round one another so as to make two revolutions, the excess of wire was cut off, and the twisted ends were gently hammered on to the bone so that no rough edge was palpable. The torn aponeurosis was stitched here and there with silk. The skin was sewn up, no provision being made for drainage. The edges of the wound were wiped over with the same solution of iodine, a gauze dressing was applied, and the limb placed on a back splint.

Mr. Evans said that it is generally stated in the text-books that the transverse fracture of the patella is due to muscular action, while direct violence is said to produce a stellate fracture. While these statements

are on the whole true, it is certain that it is not at all rare for direct violence to produce a transverse fracture, as in this case. When direct violence causes a fracture without rupture of the aponeurosis there is no separation of the fragments, the fracture being usually stellate, and wiring is not necessary; but the treatment for ordinary cases of fracture of the patella should certainly be wiring. The only exceptions are cases in which the age or the general health of the patient renders the operation undesirable. The incision employed in this case appeared to him to be the best. When the late Lord Lister first wired the patella he employed a vertical incision, but it is well, Mr. Evans thought, to keep away the incision in the skin from the neighbourhood of the fracture. It is always necessary to cut away the portions of the torn aponeurosis which overhang the fractured surfaces, for they may materially interfere with union. The exact method with which the wires are inserted, he considered, matters little, the only essential point being that the fractured surfaces are brought together and kept in good apposition. The wire may surround the patella or it may be inserted as in the operation he had just performed, but it is important that it should not encroach on the articular surface. If the operation has been performed with full antiseptic precautions there can be no need to drain the wound; in fact, the drainage tube itself may form a channel for the admission of germs to the wound. It is desirable, he pointed out, to keep the limb on a back splint until the patient has fully recovered from the anæsthetic, but then it is better removed, for there is no fear that the patient will move the joint too much, and the absence of the splint will hasten the return of mobility to the limb.

The patient was kept in bed for a month after the operation, and for the latter half of this period massage was daily employed. When the patient left the hospital six weeks after admission, he could walk as well as before the accident, possessing full power of flexion and extension of the knee.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD THURSDAY, JUNE 13TH, 1912.

The President, Dr. P. S. ABRAHAM, in the Chair.

DR. TOM ROBINSON showed (1) a man, æt. 46, with a severe attack of generalised, eczematous dermatitis, which had lasted for about five weeks with much irritation. Twelve years ago he had a similar attack. There was some tendency to dryness of the skin, and some of the glands were enlarged.

The PRESIDENT remarked upon the multiple causation of these cases, and recommended mild antiseptics and emollients in their treatment.

Dr. DAVID WALSH thought that many of the typically recurrent cases were frequently associated with the presence of a cardiac murmur. In the present case the pulse was compressible, and the heart sounds were weak. Defects of the circulation, acting in conjunction with changes of external temperature, might well be responsible for the cutaneous eruption.

(2) A case of alopecia areata in a child, æt. 10.

Dr. WALSH showed (1) a woman, æt. 65, with keratosis follicularis best marked upon the buttocks and thighs. There was considerable irritation of the affected parts, and the skin elsewhere showed some signs of senile degeneration. Her general health was good.

The PRESIDENT remarked that lichen pilaris, of which this was an exaggerated form, was common upon the lower limbs, but it was impossible to say why it should commence at this age.

(2) A microscopic specimen from a case of chronic eruption upon the pubis in a young man who had been out in San Francisco. The patch was reddened, and had become moist at times. The exact nature of the fungus obtained by scraping was not ascertained, as it could not be cultivated, but it consisted of short,

budding elements, no mycelium being visible. The only case at all resembling this that the exhibitor could find an account of was the one reported by Dr. Whitfield. (*Brit. Journ. Derm.*, 1908, p. 274.)

Dr. NORMAN MEACHEN showed a girl, æt. 9, with chronic eczema of the face that had existed since the age of six months. At one time she was in a children's hospital with the disease in the bends of the joints. There was quite an appreciable amount of infiltration present, and part of the facial eruption was not unlike a lupus clinically, but no nodules were seen. The child's health was good, and there was no history of consumption in the family. Up to the present, the disease had proved peculiarly resistant to treatment.

The PRESIDENT said that he would try the compound petroleum ointment combined with glycerine of starch in this case.

The question of the removal of any adenoid growths that might be present was discussed by several of the members.

Dr. D. VINRACE showed a young woman with psoriasis of some years' duration, in whom an acute attack of pityriasis rosea had supervened. The characteristic lesions of the latter condition were strikingly manifest upon the trunk, some of them showing up well in contrast to the older patches of psoriasis.

The PRESIDENT gave a short *résumé* of our present knowledge of pityriasis rosea, and he recommended mild sulphur applications.

Dr. H. SAMUEL drew attention to the similarity of the affection to an exanthem, especially as regards the apparent immunity conferred by one attack.

Dr. WALSH agreed that it was a self-limited affection, running a definite course, although no organism had been found.

Dr. AGNES SAVILL thought that the duration was often very variable, and that it was sometimes followed by urticaria.

Dr. J. D. P. MCLATCHIE showed (1) a young woman with a palmar syphilitic affecting both hands. The condition was improving under appropriate treatment.

(2) A woman with typical scarring around the mouth as the result of late syphilis.

Dr. R. W. BRIMACOMBE exhibited a young woman, æt. 27, with curious, irregular patches of brownish-yellow pigmentation upon both cheeks and also upon the chest. The condition began upon the face two years ago. The catamenia were regular, and there was no uterine disease. Her general health was good. The patient had rather dark hair and eyes.

Several members remarked upon the similarity of the pigmentation to that of the chloasma of pregnancy, and all were agreed as to the interest of the condition, which did not appear to be easily explicable in the present case.

THE ROYAL SOCIETY.

MEETING HELD JUNE 27TH, 1912.

The following is an abstract of the paper and conclusions by A. W. PORTER, F.R.S., and F. W. EDRIDGE GREEN, M.D., F.R.C.S., on

NEGATIVE AFTER-IMAGES AND SUCCESSIVE CONTRAST WITH PURE SPECTRAL COLOURS.

A definite portion of the retina was fatigued by steadily gazing at an isolated region included between two definite wave-lengths in the Edridge Green colour perception spectrometer. After the fatiguing light had been viewed for a period of about 20 seconds, the eye was turned to a screen on which a spectrum was situated, so that the after-image formed a band running right across the spectrum on the screen and occupying its centre. Experiments were also made with the spectrum replaced by monochromatic bands and on the appearance of the sodium flame after fatigue to various colours.

The first point which was evident was the very great importance of the intensity of the light which was used, especially in relation to the reacting light.

(1) Very little effect was produced, except when the intensity of the reacting light was the same or less than that of the fatiguing light.

(2) The effect was chiefly noticed on the less luminous portions of the spectrum; for instance, after fatigue for yellow there was very little effect in the yellow, but considerable effect in the violet.

(3) The after-image is not surrounded by the primary colour.

(4) The effect of fatiguing the eye with a monochromatic region produces a uniform grey band across this region, when both fatiguing and reacting lights are of the same intensity.

(5) The after-image does not change colour on fading.

(6) Violet was the most affected after fatigue for red.

(7) An after-image is seen in the absence of all external light.

(8) Except after fatigue by a very bright light, as, for instance, direct arc through coloured glass, yellow does not change to green after fatigue to red, or to red after fatigue to green.

The same is found with the sodium flame, though the after-image was strongly marked on each side of it.

(9) The after-image, even in the absence of all external light, is always darker than the surrounding visual field.

(10) The complementary to the exciting light is never strengthened in the spectrum on the screen by the after-image.

These facts cannot be explained on either the Hering or Young-Helmholtz theories. The explanation on the Edridge-Green theory of colour-vision is the same as that given for other facts of simultaneous contrast.

SPECIAL REPORTS.

THE INFLUENCE OF RECENT RESEARCH ON THE TREATMENT OF SYPHILIS.

A DISCUSSION on this subject took place recently at the Seventh International Congress of Dermatology and Syphilology, held at Rome, April 8th to 13th, 1912.

Professor NEISSER (Breslau), in opening the discussion, remarked that syphilitic infection can be diagnosed by the presence of the spirochæte and by serum diagnosis, even in the absence of definite clinical symptoms. It is experimentally proved that the spirochætes have generally spread in the body before the chancre is clinically appreciable. Experimental research has shown that in diseases caused by trypanosomes and spirochætes, a complete cure is more easily attained the earlier treatment is commenced. In the case of syphilis, treatment should be begun as soon as possible after the diagnosis is confirmed, with the object of effecting a radical cure. In doubtful cases the spirochæte must be looked for and the serum tested. But, treatment may also be commenced without a definite diagnosis (under certain conditions, such as that of married men), for it is possible by means of repeated serum diagnosis to distinguish between latent syphilis and cure of the disease, even in the absence of visible symptoms. It is impossible to prove that syphilis leaves any real immunity after cure; reinfection may take place in both animals and man, and the second attack may follow the same course as the first. On the other hand, generalised syphilis, especially in the first years of infection, causes a high degree of resistance of the skin to fresh infection. However, by energetic inoculation with material rich in spirochætes, this resistance of the skin may be overcome and superinfection occur. Before syphilis has become constitutional (in the first weeks after infection) inoculations, either with autogenous or heterogenous virus, may produce new chancres. Again, after several years, when the disease is on the way to cure, inoculation may also give positive results when made in a region which is not influenced constitutionally. Thus, superinfection only occurs under certain special

conditions. Tissues not yet infected and impregnated with the virus react like primary infection; tissues affected with secondary, tertiary or malignant syphilis present corresponding products of superinfection. However, in advanced tertiary periods the products of inoculation may closely resemble primary sores; this may be due to return of the normal reactive power of the tissues. As regards serum therapy, no method of passive or active immunisation has yet been discovered; but the researches of Kraus and Spitzer seem to show that immunising treatment is possible. It is also possible that immunisation may be attained by means of pure cultures of spirochætes, provided that these microbes can be cultivated with certainty and in sufficient quantity. At whatever time after infection treatment is begun (preventive before propagation of the spirochætes, or abortive as soon as possible after generalisation), general treatment should always be carried out. Serum diagnosis is essential in treatment, because the clinical symptoms do not give sufficient evidence of the state of health of a person infected with syphilis. A positive reaction is a proof of infection, a negative reaction, although of less value, gives important information as regards diagnosis and treatment. Serum diagnosis has shown that the usual treatment of syphilis has hitherto been generally insufficient. This accounts for the frequency of post-syphilitic affections, and also for the rarity of re-infection. Treatment should not only aim at the disappearance of clinical symptoms, but also at the production of a permanent negative reaction. General treatment should, therefore, be as energetic as the patient can support, for the therapeutic action depends on the quantity of the medicament introduced into the organism. Injections are preferable to inunctions and internal medication, because they cause less harm to the body. The true anti-syphilitic medicaments which have the power of killing spirochætes are: (1) Mercury; (2) atoxyl, arsenophenylglycin, and salvarsan; (3) antimony. Iodine and quinine are much less certain. As regards human therapy, atoxyl is contra-indicated on account of its affinity for the optic nerve. Mercury, arsenophenylglycin and salvarsan are the most powerful remedies. As regards antimony, there is no evidence as to human syphilis, but it has a spirillicidal action in animals. Although both mercury and salvarsan may cure syphilis after sufficiently energetic application, it is better to combine them. Combined treatment by mercury and salvarsan has the following advantages: (1) While the dose of each drug is non-toxic, the combined effect has a powerful action; (2) certain spirochætes are affected more by mercury and others more by arsenic; (3) the manner in which mercury and arsenic attack and destroy the spirochætes is different. By the addition of antimony the combined treatment may be rendered still more powerful. If it cannot be actually denied that Ehrlich's *therapia magna sterilisans* is possible and realisable in practice, we should, nevertheless, treat syphilis by a method consisting, on the one hand, of active spirillicidal drugs, and on the other hand, of less active drugs which hinder the multiplication of spirochætes. But, in any case, the spirochætes should remain in contact with these drugs for a year or more. If, in the course of the first year a negative reaction is established, treatment may be mitigated, but not left off. Cases of late syphilis, with or without tertiary symptoms, but with a positive reaction, require intensive treatment, because it is more difficult at this period to transform a positive into a negative reaction. The reason of this is unknown; it is possibly due to encapsulation of the spirochætes, or to the presence of these in the form of spores, either of which conditions would oppose mechanical obstacles to the action of drugs. Hence the idea of combining spirillicidal drugs with hydrotherapeutic methods, iodides, &c., with a view to break down the barriers which oppose the action of the drugs. In conclusion, Neisser gives an outline of the treatment he adopts: (1) Begin treatment as soon as possible; (2) use large doses of "606," several times repeated, intravenously; later on in com-

bination with three or four intra-muscular injections of arsenophenylglycin (0.30 to 0.50 grams weekly); (3) combine this with energetic mercurial treatment by gray oil injections or by injections of asuroil; (4) continue treatment for a year at least. After this energetic treatment, Neisser says he rarely sees "neuro recurrences," the toxic nature of which he says has not been demonstrated.

Professor HALLOPEAU (Paris) advocated the abortive treatment of syphilis, which he thought was possible within 30 days after the first appearance of the chancre. For this purpose, he recommended local injections of *hectine* (20 centigrams) in and around the chancre, combined with intramuscular injections of soluble mercurial preparations repeated daily for 30 days.

Dr. MILIAN (Paris) was of opinion that syphilis might be aborted by the above method, and also by salvarsan. With regard to the latter drug, he reported the results of 27 cases treated in the primary stage; 6 of these have shown no sign of secondary syphilis after intervals of 12 to 17 months, and one of these contracted syphilis again (re-infection). Milian remarks that re-infection is frequent after treatment by salvarsan; he has observed two cases after cure of the chancre, one case after secondary syphilis, and two cases after tertiary syphilis. He is also reported to have said that this frequency of reinfection is unknown after mercurial treatment. [This is quite erroneous, for numerous cases of reinfection have been reported after mercurial treatment.] He considers that salvarsan may cure recent tabes and leucoplakia, and cause improvement in older cases. He even thinks that general paralysis is benefited, because lymphocytosis of the cerebro-spinal fluid diminishes under salvarsan. Milian is convinced of the therapeutic value of salvarsan, but is of opinion that better results may be obtained by the addition of other drugs, including mercury, iodides and possibly antimony, on the assumption that spirochaetes which become resistant to one drug may be destroyed by one of the others. He therefore advocates the following method of treatment: (1) Four intravenous injections of salvarsan (0.30, 0.40, 0.50, 0.60 gram) during 20 days; (2) an interval of 10 days; (3) eight injections of grey oil or calomel (0.07 gram) with eight injections of benzoate of mercury (0.02 to 0.04 gram), given alternately once a week, together with 3 grams of potassium iodide daily; (4) an interval of 10 days; (5) four injections of salvarsan, as before. As regards the criterion of cure, Milian holds that neither clinical symptoms nor the Wassermann reaction are certain, and recommends a test reaction by an intravenous injection of salvarsan (0.30 gram) with subsequent serum tests at intervals. In conclusion, he considers that the new arsenical preparations may succeed where mercury has failed, but cases of syphilis may become refractory owing to the creation of arsenic resistant spirochaetes.

Professor FINGER (Vienna) remarked that formerly the evolution of syphilis was attributed to modifications in the degree of virulence of the syphilitic virus, but recent research has shown that the virulence of the virus is generally constant, and that the variations in evolution of the disease are due to differences in the soil. All attempts to attenuate the virus have so far failed; also attempts at vaccination. The old theory of immunisation and receptivity of the organism must be abandoned. The receptivity of each organ is subject to great variations of time and place, in which the quantity of virus plays a part. This explains why an organ is sensitive to a local inoculation (large quantity of virus), when it is apparently immune to a virus injected by the blood (small quantity of virus). The same organ may present variations in receptivity, and these variations may be influenced as much by external conditions, irritation, inflammation, etc., as by treatment. The manifestations may be explained by a relatively different action of the virus, by phenomena of defence, or by the power of resistance. In every organism, animal or human, organs of different types may be present, and show multiple variations, thus explaining the great diversity

in the evolution of syphilis in man and animals. In the lower monkeys, the receptivity of the skin is confined to certain regions (eyelids and genital organs), the chancre is not typical, and variations in receptivity at the point of inoculation after disappearance of the chancre account for local recurrence at the point of inoculation. On the other hand, the skin is generally unaffected by virus introduced into the blood. Of the internal organs, the spleen, medulla of bones and testicle are slightly receptive, and the other organs not at all. In the anthropoid apes the skin is receptive both to local inoculation and to virus introduced into the blood. In man, the skin reacts as in the anthropoid apes; the organs differ in receptivity in different individuals. In some rare cases there is little or no receptivity of the skin to virus introduced by the blood, associated with extreme receptivity of certain internal organs (paralysis, tabes, aortitis and sclerosis of the coronary arteries). Acquired syphilis is a disease of the tissues in which the blood transports the virus from time to time only, and thus differs from the hereditary disease, which is a disease of the blood, a true spirochætal septicæmia. The period which elapses between inoculation and infection of the blood vessels and lymphatics appears to differ in man and animals. Regional papules arising near the chancre are no doubt produced by propagation of the virus along the lymphatics and lymphatic spaces by auto-inoculation. The virus which travels by the blood is always more abundant, and penetrates all the organs and tissues, and afterwards reaches the perivascular tissue. The roseola is due to blood infection; secondary relapses to lymphatic propagation around an old syphilitic focus, which explains the corymbose grouping of the eruption. When recurrent roseola is of blood origin it resembles primary roseola; tertiary roseola is almost always due to remains of the virus which have remained latent since the primary period. Malignant syphilis is a form in which the elements have a tendency to eccentric extension and central destruction, in which latent periods between the relapses are absent and disseminated relapses occur by the blood. In these cases spirochaetes are often scanty, and the Wassermann reaction negative or feebly positive. The old idea of syphilitic immunity lasting for life must be abandoned. According to this idea, the syphilitic is sensitive to his own virus, but insensitive to external virus; but clinical and experimental facts show that efforts at immunisation are always insufficient; immunity is not complete or only transitory; there is generally only a modified reaction both to autogenous or heterogenous virus. During the first inoculation the efforts towards immunity are feeble; successive chancres may result from repeated inoculations, but changes in the cutaneous reaction are shown by shortening of the incubation period and feeble development of the later lesions, which, however, are typical. During the second inoculation period the later lesions may be less typical, but sometimes in cases of auto-intoxication they are quite typical. In the secondary period inoculation of external virus may cause papules—i.e., elements corresponding to this stage of syphilis. In tertiary syphilis, inoculation of external virus causes the same lesions as inoculation with autogenous virus. Hence, superinfections show that the syphilitic is not completely immunised at any period of the disease. His own virus and external virus cause the same clinical lesions, varying according to the reaction of the subject. But true reinfection may also occur, with a second chancre, regional adenitis, and roseola. Such reinfections may occur a few years or 10 to 30 years after the first infection. There is no doubt that cases of spontaneous cure of syphilis occur, but it is impossible to estimate their frequency. Examples of such cases are women infected after marriage, who suffer from gummas 30 or 40 years later, and are easily cured with iodides; also cases cured with a single course of mercury. But the more serious evolution of the majority of cases of syphilis makes it necessary to treat every case energetically, for we cannot distinguish between cases

which will be benign or severe, and the statistics show that the severity of syphilis is inversely proportional to the energy of treatment. Antisyphilitic remedies (mercury, iodides and arsenic) do not appear to have a directly parasitocidal action; it is more probable that they act indirectly, either, as Ehrlich suggests, by being transformed in the body into parasitocidal agents, or by acting on the soil and rendering it less receptive,—*i.e.*, by increasing the power of resistance of the cells. The persistence of the virus in regions which have undergone energetic local treatment favours the latter view. Mercury and iodides have survived the test of time. As regards salvarsan, it is still in the experimental stage; it seems superior to mercury in certain cases, such as malignant syphilis, but it possesses a certain degree of toxicity due to arsenic. Examination for spirochaetes and the facts furnished by the Wassermann reaction have modified the treatment of syphilis. By means of dark ground illumination syphilis may be diagnosed when clinical symptoms are slight and the Wassermann reaction negative. These facts bear on the question of abortive treatment, by excision of the chancre, or by energetic local treatment. The results of such abortive treatment are variable. In certain cases the symptoms of syphilis disappear, and the Wassermann reaction becomes negative. These cases are rare and may occur after mercury or salvarsan. In other cases the roseola disappears and the reaction becomes negative for six months, but after this time the reaction again becomes positive and symptoms recur, especially mucous patches of the throat, which may recur several times in spite of treatment. The Wassermann reaction may again become negative or positive, but two years after infection it remains negative. Sometimes abortive treatment only postpones the appearance of the roseola. In other cases, it has no influence on the evolution of the disease. Hitherto the intermittent method of treatment of syphilis has been based on empiricism; the Wassermann reaction is now a valuable guide, although its signification is not quite clear. The reaction is positive about the sixth week after infection, and increases in intensity up to the appearance of the roseola. During the secondary period, which persists for three or four years after infection, the reaction remains positive in most cases, but becomes negative permanently under the influence of treatment. After a relapse the reaction generally becomes positive except in relapses, which occur rapidly under treatment, and which seem more frequent since the use of salvarsan in malignant syphilis. The reaction may remain negative in spite of symptoms. After three or four years syphilis generally becomes latent, in which case there may be no symptoms and a negative reaction, or the reaction may become positive in spite of absence of symptoms. From the theoretical point of view treatment might be continued till the reaction becomes permanently negative, but it is doubtful if this object can be attained in all cases by increasing the duration and severity of treatment. The cases where syphilis has been cured without treatment or with insufficient treatment are opposed to cases of failure after energetic treatment, and if "specific" drugs only act by increasing the power of defence, it is possible that this often fails. Hence, increase in the energy of treatment should be prudent. The fact that relapses are generally due to latent microbes indicates energetic local treatment, preferably by inunctions. The diagnostic value of the Wassermann reaction is undoubted, but a positive reaction does not prove the syphilitic nature of the lesion in question. If the Wassermann reaction indicates syphilis, it gives no information on the contagiousness of the disease, and as regards the question of marriage, it is better to be guided by the clinical symptoms, the age of the disease and the previous treatment.

Professor GAUCHER (Paris), referring to "606," said that it should only be employed in certain cases, chiefly in those where mercury failed. As to the sterilisation of syphilis, he did not think this possible either with "606" or mercury. As regards the

Wassermann reaction, he considered that a negative reaction was no proof of cure, because the reaction may still be negative just before a fresh outbreak of syphilis. With regard to abortive treatment, Gaucher points out that more than a third of syphilitics only suffer from a chancre which heals quickly and a transient roseola which may escape notice, even with no treatment, but it is these patients who, after 10 or 12 years, come again with tertiary syphilis; hence, the rapid cure of the chancre and the apparent absence of secondary symptoms is no proof of abortive cure. He remarks: "How can we state that syphilis is cured by '606' when we have had only about a year's experience?" As regards the so-called reinoculations, he considers these to be chanciform syphilides. He regards "606" as a cicatrising agent only, not a cure for syphilis; six months or a year after its administration mucous patches and condylomata frequently appear, just as they do after three months in untreated cases. In conclusion, he considers "606" an active medicament, and hence less dangerous but less active; but, like all arsenical compounds they are exceptional drugs. Mercury is and should remain the fundamental treatment of syphilis.

GERMANY.

Berlin, June 29th, 1912.

At the Hufelandische Gesellschaft, Prof. Strauss gave a report on the

TREATMENT OF DIABETES BY INULIN.

He was led to this by a recommendation to give to diabetic cases vegetables rich in that substance, as in some cases not only were the vegetables well borne, but it had been observed that their use had a tendency to diminish the excretion of acetone. An inquiry then made induced the speaker to go into the matter still further, more especially as there was but little in literature to lead him to suppose that the subject was one into which much inquiry had been made. No systematic investigation had been made into the relations between inulin and acidosis. He therefore made use of the preparation in nine cases of diabetes, in five of which the disease was in a severe form, in four a milder type prevailed.

Inulin, a polysaccharide of levulose, had already been recommended by Külz for the treatment of diabetes. Naunyn later expressed a rather unfavourable opinion regarding it. He had, however, only used the pure substance in seven cases, and even in these the observations were only carried out for a couple of days in some of them. Socin, indeed, found a relatively small excretion of sugar after giving artichoke flour, and acknowledged its superiority to dextrose. It had also been found that neither the oral secretion nor pancreatic juice had the power of exciting decomposition in inulin.

The plan of procedure he had adopted during the last half-year was the following:—An attempt was first made by strict diet to bring about a state of aglycosuria, and if this failed the sugar was reduced to the lowest degree possible the case admitted of. Then, to the diet made use of hitherto, and which generally consisted of vegetables, eggs, fat, coffee, tea, and bouillon (only in a few cases a little meat was allowed). Whilst this diet was kept up, for certain periods—mostly for from six to eight days—a daily addition of 100 gm. of inulin was made. The administration was generally along with vegetables, prepared with salt and butter, and occasionally as an addition a fruit dish free from sugar. Notice was constantly made of the using up of the inulin; the fæces, in regard to the carbohydrate contents, and in some cases the contents of the stomach, were also examined.

The first case was that of a student, æt. 22. He was under observation from August 15th to October

10th. During that period both sugar and acetone diminished; the patient felt quite well, with a total gain in weight of 16 lbs.

The second was that of a married woman, *æt.* 39. The disease began from four to five months ago. Admitted November, 1911, discharged December 30th same year. In this case there was no appreciable improvement, but the treatment was interrupted, as the patient had to leave the hospital on account of domestic affairs. But the speaker was of opinion that the diet had a distinct influence on the excretion both of sugar and acetone.

Case 3, female, *æt.* 45. Admitted January 9th of the present year. The illness began, or rather sugar was first found in the urine, three years ago. Under treatment till March 5th. The case was one of medium severity. With a strict diet the urine could be made free from sugar. During the inulin period sugar was present, but only in small quantity. On every occasion on which oatmeal was given the quantity of sugar increased.

Case 4, male, *æt.* 48. Under strict diet the urine could be brought to be quite free from sugar. The case was complicated by tuberculosis. After giving inulin four days there was still no sugar and the acetone disappeared. A review of these four cases showed that 100 gm. inulin was not only well borne, but that it led to a diminished excretion of sugar, as compared with the period when no carbohydrates were given, and also a favourable influence on the acidosis was observable. Moreover, the patients mostly gained in weight. In one case the treatment was begun when the patient was in too advanced a stage of the disease for any improvement to be expected.

In the six milder cases tolerance of the 100 gm. of inulin was always seen. Any acidosis present almost always disappeared. Here also there was no diminution in the comfort with which the treatment was borne.

HUNGARY.

Budapest, June 29th, 1912.

At the last meeting of the Budapest Royal Society of Physicians and Surgeons Dr. Alapi read a paper on

CALCULI IN THE KIDNEYS OF INFANTS.

During the last two years the reader has made 160 necropsies, and has observed at least 70 cases of renal calculi in one form or another in nurselings. Amongst these there was not one case of biliary calculus. Renal lithiasis may occur in the form of uratic dust which may be observed as yellowish striæ in the pyramids. Gravelly concretions and calculi are also found, and in some cases may be observed during life in the urine especially in extreme cases of inanition and malnutrition. A condition known as inanition fever has been described by American practitioners, and is found in newly-born children who do not receive a sufficient supply of milk or fluid nourishment. This fever is to be attributed to the deposition of uratic material in the kidney, though no evidence may be found in the urine. Bókay Tános points out that normally during the first few days of life, the urine is extremely rich in uric acid, and that by the end of the second week its more usual characters are assumed. The reader has more particularly observed 23 cases, of which 14 were boys and 9 were girls. The majority of the cases occurred under the age of six months, and all were due to bad feeding, inanition, and "misère physiologique." Of the total number 20 were reared by hand. In addition to the uratic dust observed in the pyramids, gravel and hard calculi, angular or rounded in form, were found in the pelvis of the kidney and calices. They consisted of urate of sodium, and it is possible that troubles arising at a later period of existence may have their ultimate origin in such early formed calculi. In some instances pyelitis or hydronephrosis was observed. The symptoms were obscure as the regular signs of renal colic were absent. Crying, general uneasiness, screaming during micturition or retention of urine may all be symptoms. The prognosis should be reserved. Fatal results may follow, in case of survival renal colic, or vesical cystitis may occur.

Prophylactic treatment.—Should be observed in insisting on ample and proper nourishment at the earliest period of life, although overloading of the stomach should be avoided. Weaning should not take place too soon, and during febrile attacks plenty of water should be given to facilitate the excretory action of the kidneys. If the stomach be extremely intolerant of food, etc., lavage of that organ or injections of artificial serum may be employed. If the lithiasis be confirmed the child when older may undergo a "cure" at the corresponding baths.

ON THE OCCURRENCE OF KOPLIK'S SPOTS IN MEASLES.

Dr. Bauer looked for spots on the buccal mucous membrane, first described by Koplik as preceding by some days the general eruption of measles and found them in 27 cases. In one case they preceded the eruption by six hours, in 11 cases by one day, in 5 by two days, in 3 by 1½ days, and in 2 by four days. The spots were generally situated on the mucous membrane of the cheeks opposite the molar teeth, but occasionally on the lips—beginning as slightly raised, bluish-white, circular, sharply-defined points, in size less than a pin's head, and surrounded by a narrow red areola. In a few days they generally increase slightly and become more prominent, and the areola enlarges and becomes more irregular in outline. Their number varied between 6 and 20, and the time during which they persisted from two to six days. They were not marked just before, or at the time of the general eruption. They were not present in 14 cases (7.1 per cent.). Since they are never seen in other conditions accompanied by fever, they are of the greatest importance for the early diagnosis of measles. Bauer claims that the buccal eruption in measles was first mentioned by Gerhards, and that their importance was recognised by Filatow in 1895, a year before their independent discovery by Koplik. In Hungary the first consideration to this symptom was given by Prof. T. Bokay, who exhibited several cases with marked Koplik's spots in 1896, in the Medical Society.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

MEDICAL INSPECTION OF SCHOOL CHILDREN.—Dr. Meikle has issued his report of the work done during the school year 1910-11. There are now 62 schools under inspection in Edinburgh, with an average roll of 46,639 scholars. Inspection takes place on admission to school, at nine years, and on leaving school. In all, 23,641 children were examined. Duncan Street special school was opened in September, 1910, and there is thus now accommodation for 160 pupils in the special classes under the Board. During the year 3,605 notices were issued to parents in connection with 13,349 pupils examined; 25 per cent. related to lack of cleanliness, 40 per cent. to skin and dental disease, and 19 per cent. to defective vision or eye disease. Insufficient food, clothes, and cleanliness—evidences of neglect—are dealt with thus:—(1) Child neglect; (2) child relief. Under the first head neglect is classified under seven types—insufficient food, insufficient clothes, insufficient boots, neglect of medical treatment, vermin of head, vermin of body and dirt. In these cases warning cards are issued to the parents; failing these being effective the parents are summoned to the Board; eventually cases are referred to the Procurator Fiscal for prosecution. The warning cards do much to check neglect, and only 21 parents were summoned to the Board, and one convicted at the Sheriff Court. Child Relief.—If the Board decides that a case is one of poverty, the children are fed by the Board; since January, 1911, about 133,885 meals have been supplied at a cost of 2d. per meal. The food is distributed from the Board's cookery centre to the various dining centres. The maximum number on the feeding list was 1,599, and there were also 380 children who paid, and 280 who were paid for by the Parish Council. Applications for clothes and boots

are forwarded, after inquiry, to the Police-aided Clothing scheme. The medical inspection of school children has, it is stated, greatly increased the work of the special departments of hospitals and of the dispensaries. Ringworm is no less prevalent than in previous years. At a given date 300 were absent from school owing to this cause. Among the difficulties in dealing with ringworm is that of securing a proper certificate that the child is fit to return to school, and to meet this it has been decided that the duty of giving this certificate is to devolve on the School Medical Officer. At the special school in Laureston for ringworm cases there are facilities for microscopic examination of the hair. Though only the more serious cases of defective vision are notified, about 10 per cent. of school children come under this head. These cases are treated at the infirmaries and dispensaries, and greatly increase the work there; the information obtained, also, is not available for the School Medical Officers. For these reasons the whole question of defective vision requires consideration in connection with the Government grant for treatment in connection with the medical inspection of children. There is in Edinburgh no adequate means of dealing with dental defect, and the Board are advised to take this into consideration also in connection with the grant. Among other matters referred to in the report are the Wednesday afternoon inspection of children who are absent from school, and who are not being medically attended elsewhere. There were 1,382 such, more than half being skin diseases. There are also the usual statistical tables, with relevant notes. It is of interest that out of 467 cases in which lung disease was present, pulmonary tuberculosis was detected in only eight cases. About 2.5 per cent. of the children had no vaccination marks.

PORTRAIT OF DR. R. W. PHILIP.—The twenty-fifth anniversary of the opening of the Royal Victoria Dispensary for Tuberculosis is being fittingly celebrated by the presentation to Dr. Philip of his portrait. Dr. Philip's pioneer work in connection with tuberculosis is too well known to demand recapitulation here; it is enough to say that what is generally known as the "Edinburgh system," which has recently received the *imprimatur* of the Departmental Committee by being substantially followed on their recommendation, owes its existence to the administrative ability of Dr. Philip. Dr. Philip's portrait will be placed in the hall of the dispensary. The Honorary Treasurer to the Fund is Mr. C. E. W. Macpherson, 6 N. St. David Street, Edinburgh.

NATIONAL INSURANCE ACT.—The Scottish National Insurance Commissioners have appointed Dr. Currie, Medical Officer of Health for Stirlingshire, and Dr. Matheson Cullen, Edinburgh, to the posts of Principal and Assistant Medical Officers at salaries of £800 and £500 a year respectively. We regret that through inadvertence it was stated in this column last week that Dr. McLeary had received one of these appointments. He holds office, not under the Scottish, but under the English Insurance Commissioners. Dr. Cullen has for several years been a member of the Edinburgh Town Council, a magistrate of the city, and convener of the Public Health Committee. His appointment necessitates his vacating his position on the Town Council, and steps are being taken by the Executive Ward Liberal Committee to select a candidate as his successor. The annual meeting of the Edinburgh Branch of the British Medical Association was held in Edinburgh on June 28th. There were upwards of a hundred members present, representing Edinburgh, Leith, the Lothians, Roxburgh, Berwick, Peebles and Selkirk. It was unanimously resolved: (1) "That the meeting express its extreme disapprobation of the action of Dr. Matheson Cullen in accepting one of the paid Medical Officerships for Scotland under the National Insurance Act." (2) "That the meeting expresses its strong disapproval of the action of Sir James Russell in agreeing to act on the Provisional Local Insurance Committee as medical representative of the Town Council." The acceptance of both these appointments is in direct antagonism to the declared and deliberate policy of the British Medical Associa-

tion and of the Scottish Medical Insurance Council. The meeting further unanimously resolved to express its strong disapproval of Dr. Norman Walker's refusal to place his resignation as a member of the Scottish Advisory Committee in the hands of the Scottish Medical Insurance Council, to be used if and when found to be wise and expedient, and to call on him to explain to the profession the reason for such decision on his part. It should be stated in explanation of this resolution that Dr. Norman Walker is the Direct Representative of Scottish medical practitioners on the General Medical Council. The practitioners in this area, being a section of his constituents, are of opinion that his action is not only diametrically opposed to the wishes, but is also harmful to the ideals of the profession and to the interests of the public. Further, of the eleven medical members of the Scottish Advisory Committee, Dr. Walker is the only one who has refused to give an undertaking that he will resign his position on the Advisory Committee if called upon to do so by the Scottish Medical Insurance Council.

TYPHUS FEVER IN GLASGOW.—During the past week or two there has been a slight outbreak of typhus fever in Glasgow. The infected area is on the south side of the city, and there have been between twenty and thirty cases notified. This resurgence of the disease serves to remind one that in the annals of Glasgow, as of Edinburgh, typhus fever has played a prominent part among contagious maladies. It became virulent in the city at the time of the first Irish immigration, and in the great epidemic of 1847 accounted for over 4,000 deaths. The last great epidemics were in 1864, 1865 and 1868, the deaths being 1,138, 1,177 and 970 respectively. The quarter of the city affected in the present instance harbours large numbers of alien immigrants.

BELFAST.

BENN ULSTER EYE, EAR, AND THROAT HOSPITAL.—The annual meeting of this Institution was held on June 25th, the High Sheriff of Belfast, Mr. James Johnston, in the chair. During the year 2,348 new patients, in addition to 455 from the previous year, attended the out-patient department, the total attendances having been 7,535. Three hundred and sixty patients were admitted into the wards from the following counties:—Antrim (including Belfast) 196; Londonderry, 24; Monaghan, 18; Fermanagh, 4; Donegal, 4; Tyrone, 36; Down, 40; Armagh, 38. The work done during the past year was of the usual kind. There were 35 operations performed for cataract, in addition to 15 for cataract produced by injury to the eye. Anæsthetics were administered for 220 operations of various kinds for the relief of eye, ear and throat troubles. A very large number of patients were tested and fitted with spectacles, a most important part of the work of an eye hospital. The Spectacle Mission has co-operated with the medical staff in assisting poor persons to obtain glasses free of charge. A large amount of work has been done in the nose and throat department, especially for the relief of obstruction to free nasal breathing, and for the cure of deafness caused by post-nasal obstruction. The Committee regret that they have lost the services of Miss Middleton, their Lady Superintendent, who has managed the hospital so successfully for over 20 years. Miss Middleton was the recipient of a small presentation from members of the Committee and the medical staff.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE MEDICAL DEFENCE UNION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR,—I am the debtor of your correspondent Dr. S. J. Ross, of Bedford, for his information and suggestions. In response to his query, I have no intention of resigning my membership of the Medical Defence

Union, the fact of my letters to the Gen. Sec., Dr. A. G. Bateman (*vide* THE MEDICAL PRESS AND CIRCULAR, June 8th, 1910, and May 29th and June 12th, 1912) being allowed to pass unchallenged, indicating a call for reform, from which I do not wish to be disfranchised.

I may here remind the Council that on November 7th and December 6th and 19th, 1906, I submitted to them a series of questions, a copy of which I beg to enclose, but failed to get any answer or satisfaction from them, and on April 8th, 1907, I gave the Council notice of motion and of questions to be put at the annual meeting, and have done so yearly till now.

Such notices, however, having always been ruled "out of order" on the alleged disabilities of the meeting, which the Council has elected to call under Article 28 of the Memorandum of the Association.

For the first time during my 26 years of membership the notice convening the annual meeting (the 20th inst.) and the agenda have been marked "Statutory," the motive obviously being to limit the scope of the meeting to mere formal business and thus to put out of court the discussion of debatable items, my notice of motion (*vide* THE MEDICAL PRESS AND CIRCULAR, June 12th, 1912) being ignored as usual. Early in the meeting in question I endeavoured to raise some points of order, only to be parried, and after listening for half an hour to a presidential address which, however interesting, was not strictly relevant to the Union's work, I ventured with every deference to ask the President how long he proposed favouring us? My question, however, was not received kindly, and the address concluded some ten minutes later. I trust it will be printed and circulated, as strangers were asked to withdraw and there was not, I believe, any recognised shorthand reporter present.

Those who were at Brighton last year may remember that I similarly raised points of order and asked questions at the opening of the meeting, but that the then president peremptorily declined to deal with them and proceeded to the next business. He talked out time with a long and instructive presidential address, and hurried through the rest of the business to enable him, as he ingeniously explained, to catch his train. It was to avoid the possibility of such undue haste or the adjournment of the meeting that I intervened and not out of the remotest discourtesy to the President. Indeed, I did myself the honour of moving a vote of thanks to him at the conclusion of the meeting.

The members may share my view that the duty of the Council—on this hitherto the only chance the ordinary member has of being present and taking part—is to give an account of their stewardship and further it would be an act of grace if they abstained on matters in which they are personally involved from any active part or partisan spirit, voting and the like.

The voice of an annual meeting should be that of the *general body of members* and it should be suitably convened and so conducted. Even exclamations by the Council of assent and dissent are better avoided.

As my motion according to the Council's decision can only be considered at a meeting convened under Article 17 of the Memorandum—upon a requisition in writing signed by 20 members, I shall be grateful to any member who will fill in the form and post it to me.

Such meeting need not of necessity be held now, but the requisition can be held in readiness for this time next year. If the Council elects to hold also a so-called "Statutory" meeting, the latter can be taken on the same occasion.

I am, Sir, yours truly,
DENNIS VINRACE.

88a, Gower Street, London.

June 22nd, 1912.

The form of requisition will be found on page v. of Advertisements.

[The rules which govern incorporated bodies are definite and cannot be contravened if the society's actions are to remain valid. This observation applies to the Statutory Annual General Meeting, and it is to be presumed that the officials of the Union will act in

exact accordance with rules. We think it fair, however, to insert our correspondent's letter.—Ed. M. P. and C.]

OBITUARY.

LIEUTENANT-COL. F. E. MCFARLAND.

WE regret to announce the death of Francis Edward McFarland, which took place on June 24th, at his residence, Chichester Park, Belfast. The deceased had been in failing health for some months, so that his death was not quite unexpected. He was the only son of the late Mr. Edward McFarland, and was born in Dublin. He received the diplomas of the Colleges of Physicians and Surgeons of Ireland as far back as the year 1858. Immediately after qualifying he determined to enter the Army Medical Department. In this service he remained for a period of 20 years, the greater part of which was spent in India. He performed his duties so as to merit the approval of all with whom he came in contact. Preferring private practice to military life, he came to Belfast at the completion of his term of service, and soon built up an extensive high-class practice. He was universally beloved by his patients and the public, and by his upright and honest dealing he soon won the esteem and respect of his brethren in the profession, who elected him to the high office of President of the Ulster Medical Society for the session 1894-5. He was also elected Consulting Physician to the Ulster Hospital for Women and Children, an Institution in which he took the liveliest interest during the remainder of his life. Of a modest and retiring character, he took no active part in the public life of his adopted city, but was ever to the front in the quiet performance of charitable work for the poor. He took a great interest in the cause of temperance, and his unostentatious efforts in this direction will not soon be forgotten. He was the type of a good, old-fashioned, genial and sympathetic general practitioner. Much sympathy will be felt with his widow and family.

DR. R. PARAMORE, OF LONDON.

A FAMILIAR figure in the West Central district of London has been removed by the sudden death of Dr. Richard Paramore, which took place last week at his residence in Gordon Square, Bloomsbury. The deceased, who qualified as L.S.A. in 1870, became M.R.C.S. in 1872, and took the M.D. Brux. in 1884, with honours in clinical medicine. Dr. Paramore held many local appointments, including those of Physician to the Homes of Hope and to the Somers Town Blind Aid Association. He was also District Medical Officer to the Post Office. He was the author of numerous works on health subjects and temperance, as well as a frequent contributor to the medical journals. He leaves two sons, both of them members of the medical profession, to mourn his loss.

DR. WILLIAM MURRELL, OF LONDON.

IT is with the deepest regret that we have to record the death of Dr. William Murrell, Senior Physician to the Westminster Hospital, which took place on Friday last at his residence in Welbeck Street, W. The deceased, who studied at University College Hospital, qualified as L.S.A. in 1874, becoming M.R.C.S., L.R.C.P., in 1875. He took the M.D. Brux. in 1879, and was elected F.R.C.P. Lond. in 1883. Quite early in his professional career, Dr. Murrell made a name for himself in the direction of experimental therapeutics and pharmacology, and his work at the Brompton Hospital and elsewhere was speedily recognised by his early election to the staff of the Paddington Green Children's Hospital and subsequently to the Westminster Hospital, where he was Lecturer on Clinical Medicine and *Materia Medica* for many years. He was Examiner in *Materia Medica* to the Universities of Aberdeen, Edinburgh and Glasgow, as well as at the Royal College of Physicians of London. Dr. Murrell

was an honorary Fellow of the Medico-Chirurgical College, Philadelphia, Lauréat de l'Académie Médecine, Paris, and a member of the Faculty of Medicine of the University of London, and he was also a major of the Royal Army Medical Corps.

Dr. Murrell was always a staunch friend and supporter of this JOURNAL and his contributions thereto were written in that crisp and breezy style which characterised all his writings. Only a short while ago his well-known book "What to do in Cases of Poisoning," reached its eleventh edition. He was the editor of Fothergill's "Practitioner's Handbook of Treatment," which reached its fourth edition in 1907.

His loss will be keenly felt by the Westminster Hospital Medical School Staff, of which he was such a distinguished member, as well as by a wide circle of friends in the medical profession.

REVIEWS OF BOOKS.

SURGICAL TREATMENT OF LOCOMOTOR ATAXIA. (a)

THE author's thesis is that in male subjects in every case of this disease, without exception, an abnormal condition of the urethra exists, and that by treatment directed to this condition many of the symptoms of the disease may be cured or alleviated. The urethra is, therefore, carefully examined in every case by means of a special instrument. The lesions usually found are erosions, granulations and strictures. In tabs we have to do with a nervous defect which leads to degeneration of the posterior columns of the cord. This defect is acquired through the agency of the syphilitic virus. The changes occurring in this disease are primarily due to irritation of peripheral nerves. The author in this monograph certainly makes out a good case for urethral irritation as a causal factor in producing the symptoms associated with locomotor ataxia. He gives a series of cases reported to the New York Academy of Medicine in 1908, and these are certainly very convincing. The records of cases treated by the author at the Charcot Clinic of the Salpêtrière Hospital, Paris, are also very striking. The chief operative procedure adopted was dilatation of the urethra in practically every case. It would certainly seem as if a ray of hope were at last shining in upon this terrible disease which, even under prolonged iodide treatment, is a very hopeless condition. The book deserves to be carefully studied. The views expressed in it are certainly novel, and are worthy of being put to the test by those who have cases of locomotor ataxia under their care.

BRONCHIAL ASTHMA. (b)

IN this little book the author charges full tilt against the view that bronchial asthma depends upon spasm of the bronchial walls. He holds that the condition is due to an obstruction not merely of the smallest, but also of the larger and even the largest tubes by morbid products. These morbid products are the "spirals" which are produced in the small bronchi by degeneration of epithelium and exudation and are detached and pass into the larger tubes where along with others they tend to form an obstruction. Some degree of cardiac failure may lead to swelling of the bronchial walls and precipitate a paroxysm.

In spite of a powerful denunciation of the "spasm" theory, we are informed that a few whiffs of chloroform, etc., may be effective in a purely nervous asthma. We confess to some difficulty in understanding just what the author means in this instance; and through the book he seems to us to fail in driving home with sufficient clearness what lesson he means

(a) "A Surgical Treatment of Locomotor Ataxia." By L. N. Denslow, M.D., Fellow New York Academy of Medicine; late Physician, Diseases of the Skin, Bellevue Hospital, New York; late Professor, Genito-Urinary Surgery and Venereal Diseases, St. Paul Medical College. Crown 8vo., pp. x. and 118. London: Baillière, Tindal and Cox, 1912. 3s. 6d. net.

(b) "Bronchial Asthma: Its Pathology and Treatment." By J. B. Berkart, M.D., late Physician to the City of London Hospital for Diseases of the Chest, etc. Revised and abridged third edition. Pp. vi. and 150. Oxford University Press, Henry Frowde, 1911.

his illustrations to convey. We find no mention of eosinophilia in the blood, although its existence in the sputum is referred to.

Successful results in the treatment with anti-diphtheric serum of asthma due to a fibrinous exudation are recorded.

If the author, to our mind, has not proved his case he has, at least, done good service in calling attention to the importance of trying to find a definite cause for the dyspnoic attacks and in denouncing the indiscriminate abuse of powerful anti-spasmodics by asthmatics. We noted printer's errors on several pages.

ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM. (a)

THIS book has been written for three classes of readers, for the non-medical student of psychology, for the student of medicine as an introduction to the study of the nervous system, and for the medical man who desires to refresh his memory in considering cases of neurological interest. In a series of ten chapters Dr. Lickley has contrived to set forth the fundamental facts pertaining to the anatomy and physiology of the nervous system; and he has been highly successful in his endeavours to appeal alike to the non-medical and to the medical student of the subject. We must confess his task has been no light one, and he therefore deserves all the greater credit for having accomplished it in such a meritorious fashion. We have studied similar works with greater pretensions without learning so much as we have from a perusal of the one before us. A special feature of Dr. Lickley's book is the wealth of illustrations, many of which are printed in colour, and they number no fewer than one hundred and eighteen. This is a text-book which we can recommend to our readers with more than ordinary confidence in its teaching.

MEDICAL NEWS IN BRIEF.

The Lord Mayor at St. Thomas's Hospital.

AN anonymous gift of £20,000 was announced last week at annual prize distribution of St. Thomas's Hospital Medical School, at which the Lord Mayor and Lady Mayoress were present.

The Lady Mayoress distributed the prizes to the successful students, after which Sir Thos. Crosby, M.D., the Lord Mayor, having been welcomed by the Treasurer as an old student of the School, alluded to his former relationship with the College. Giving a word of advice to the staff and students, he said: "You are the educators of the future generation of doctors. They may not all of them stop inside this small island. They may go to the length and breadth of His Majesty's dominions. His Majesty's subjects in these far-off realms will be wholly and entirely dependent upon the skill that each individual young practitioner takes with him." Members of the profession, he added, should be more actively interested in municipal life, as by doing so they would teach many successful merchants a lesson in all those things which were useful for their fellow-citizens.

Epsom College.

THE annual general meeting of the Governors of Epsom College was held last week, at 37, Soho Square, W., under the presidency of Sir Henry Morris, Bt., F.R.C.S., the Treasurer, who was supported by Sir W. S. Church, Sir Alfred Pearce Gould, Sir Shirley Murphy, Sir James Reid, and other governors. The Chairman said that the number of boys in the College was the highest on record, and there was a waiting list for entrance. Sir Henry Morris was elected a Vice-President of the College, in recognition of his many services to the College, and of his having so indefatigably urged upon the General Medical Council

(a) "The Nervous System." An Elementary Handbook of the Anatomy and Physiology of the Nervous System for the use of Students of Physiology and Neurology. By James Dunlop Lickley, Demonstrator of Anatomy, University of Durham College of Medicine, etc. London: Longmans, Green and Co., 1912. Price 6s. net.

the expediency and the justice of permitting adequately equipped public schools to be approved as institutions in which the preliminary sciences might be studied.

Royal Society of Medicine.

THE following have been elected as officers of the Royal Society of Medicine for the Session 1912-13, to enter into office on October 1st next:—

President: Sir Francis H. Champneys, Bart., M.D.
Honorary Treasurers: Sir William Selby Church, Bart., K.C.B., M.D., and Sir Henry Morris, Bart., F.R.C.S.

Honorary Librarians: Sir Rickman J. Godlee, Bart., M.S., and Dr. Norman Moore, M.D.

Honorary Secretaries: Mr. Herbert S. Pendlebury, F.R.C.S., and Dr. E. Farquhar Buzzard, M.D.

The City Corporation and Florence Nightingale.

THE members of the City Lands Committee of the City Corporation have inspected and approved the marble statuette of Miss Florence Nightingale which it has been arranged shall be placed in the Guildhall, in the lobby, near the entrance to the Council Chamber. The statuette is the work of Mr. Walter Merrett.

Medical Sickness and Accident Society.

AT the usual monthly meeting of the Executive Committee of this Society, Dr. F. J. Allan in the chair, the accounts presented showed the business of the Society to be steadily growing, a considerable addition to the funds having been made since the beginning of the year.

A cordial vote of thanks was unanimously passed to Dr. F. de Havilland Hall, F.R.C.P., the retiring Chairman, now President, for the valuable services he has rendered to the Society during the many years he has been connected with it, and in recognition of Dr. Hall's work it was agreed to present a substantial sum to Epsom College as a permanent record of his services. The Society now has a large number of votes in Epsom College, and these are given only to members of the Medical Sickness Society or their relatives.

Royal Medical Benevolent Fund Society of Ireland.

A REGULAR meeting of the Central Committee was held on Wednesday last. The Secretary reported the death of Sir Thornley Stoker, Bart., member of the Central Committee. The following resolution was unanimously adopted:—Resolved: "That at this the first meeting of the Executive Committee of the R.M.B.F.S., of Ireland, since the lamented death of Sir Thornley Stoker, Bart., ex-President R.C.S.I., the Committee desire to record their sense of the great loss the Society and the Committee have sustained in the removal from their counsels of a colleague, who through a long series of years placed at the disposal of the fund his many gifts of heart and mind, and on whose sound judgment and advice the members of the Committee could always rely. The Committee further desire to convey to Sir Thornley Stoker's sister, Lady Thomson, and to the other members of his family, an expression of profound sympathy with them in their bereavement."

Three urgent applications, which were late for the annual distribution, were considered, and grants amounting to £26 were awarded.

The Poor-law Medical Officers' Association

THE annual meeting of the Poor Law Medical Officers' Association of England and Wales was held on the 25th ult., at the Council House, Bristol, under the presidency of Surgeon-General G. J. H. Evatt, C.B. The accounts showed a balance in hand of £88 14s., although the expenditure during the year had exceeded the ordinary income. The year had been an exceptionally trying one, owing to the activities demanded to meet the emergency in connection with the National Insurance Act, which was regarded as a serious menace to the profession.

Papers were read by Mr. J. J. Simpson on "Poor Law Medical Work as Affected by the National Insurance Act," and by Dr. C. F. S. Flemming, of Bradford-

on-Avon, on "Difficulties in the Practice of the Poor Law Medical Officer." Dr. C. W. H. Parkinson opened a discussion on "The Necessity of Union among all Medical Officers holding Part-time Appointments." The annual banquet was held the same evening at the Royal Hotel.

A Munificent Gift for the Welsh Medical School.

AS a mark of appreciation of the visit of Their Majesties to the King Edward VII. Hospital, Cardiff, last week, an anonymous donor has forwarded a gift of 10,000 guineas for the building of the new pathological wing of the institution which is to be erected for the Welsh Medical School, the joint establishment of the Hospital and University College of South Wales and Monmouthshire. It is estimated that £50,000 will be required to complete the medical school buildings.

Will of Sir Thornley Stoker.

THE late Sir William Thornley Stoker, the Dublin surgeon, of 21 Hatch Street, and formerly of 8 Ely Place, Dublin, who died on the 1st ult., left personal estate amounting to £10,315 15s., as valued for the purposes of estate duty.

PASS LISTS.

University of London.

THE following candidates have passed the third (M.B., B.S.) examination for medical degrees:—

Honours list: Evan P. Evans (*a*), Maud F. Forrester-Brown (*b*, *c*), Thomas C. Graves, B.Sc. (Vet. Sci.) (*c*), Philip H. Mitchiner (*a*, University medal), Donovan B. Pascall (*a*), Harold Rowntree (*a*), Catherine V. Turner (*a*).

Pass list: John W. Adams, Melville M. Adams, Frederick J. Anderson, Winifred Austin, Grantley Barratt, Bertie Blackwood, Joseph H. Campaign, Gilbert C. Chubb, D.Sc., William C. Dale, John L. Davies, Arthur F. W. Denning, Josiah R. B. Dobson, Macormack C. F. Easmon, Archibald Ferguson, Norman F. Graham, Arthur S. Hahn, Alexander K. Hamilton, Reginald S. Harvey, Frederic J. Humphrys, Edward L. Hunt, Charles E. S. Jackson, William H. Kauntze, Henry G. Kilner, William B. Laird, Andrew B. Lindsay, Martin W. Littlewood, Jivraj N. Mehta, Ernest S. Miller, Harold A. Moody, Richard N. O. Moynan, Alfred A. E. Newth, Edgar L. R. Norton, Bernard R. Parmiter, Richard D. Passey, Edward H. Roberts, Kenneth Robinson, Samuel P. Rowlands, Edward A. Seymour, Bernard S. Simmonds, Arthur H. Thomas, Thomas A. F. Tyrrell, and Francis S. Williams.

(*a*) Distinguished in Medicine; (*b*) Distinguished in Pathology; (*c*) Distinguished in Forensic Medicine.

University of Sheffield.

THE following examination results have been published (July 1st):—

M.B., Ch. B., Final Examination (Part B. completing Examination).—John P. Mathews (with distinction in obstetrics and in medicine, and clinical gold medal). (Part A).—John Davidson, H. S. Dufty, J. E. Stacey (with distinction in public health and in pathology), L. E. Sutcliffe.

Diploma in Public Health.—Marion H. Archibald, and Cyril Banks.

University of Durham.

AT the Convocation, held on June 25th, 1912, the following degrees were conferred:—

Doctor of Medicine.—Helen G. Clark, M.B., B.S., B.Hy., D.P.H. Durh., Sebert F. St. Davids Green, M.B. Durh., Duncan M. Johnston, M.B. Durh., Chas. G. Kemp, M.B., B.S. Durh., Charles F. M. Saint, M.B., B.S. Durh.

Doctor of Medicine for Practitioners of Fifteen Years' Standing.—William J. M. Barry, M.D. Brux., M.R.C.P., E., L.R.C.P. and S., L.F.P.S., G., Lillian V. Cooper, L.R.C.P. and S., L.F.P.S., G., Charles Corben, M.R.C.S., L.R.C.P., Arthur E. Dodson, M.R.C.S., L.R.C.P., L.S.A., Edward G. Gibbs-Smith L.R.C.P., I., L.S.A., D.P.H., Herbert

E. Goulden, M.R.C.S., L.R.C.P., D.P.H., Charles G. Higginson, M.A., M.R.C.S., L.R.C.P., L.M.S.S.A., Richard H. King, M.R.C.S., L.R.C.P., James C. McWalter, M.A., L.M., L.A.H., F.R.C.P. and S., G., D.P.H., Robert Odell, M.R.C.S., L.R.C.P., F.R.C.S., E., Edward A. B. Poole, M.R.C.S., L.R.C.P., L.S.A., and John R. Russell, M.R.C.S., L.R.C.P.

Master of Surgery (M.S.).—Charles F. M. Saint, M.B., B.S.Durh.

Bachelor of Medicine (M.B.).—John B. Alderson, Evelyn A. Constable, Norman Hodgson, Harold L. James, James Kerr, Francis J. Lidderdale, Lionel G. Pearson, Fred Phillips, B.A., Thomas C. Storey, Carl J. V. Swahnberg, and Samuel K. Young.

Bachelor of Surgery (B.S.).—Oscar F. D. Airth, M.B., Ronald G. Badenoch, M.B., Evelyn A. Constable, Reginald C. H. Francis, M.B., M.R.C.S., L.R.C.P., Norman Hodgson, Harold L. James, James Kerr, Francis J. Lidderdale, Fred Phillips, B.A., Thomas C. Storey, and Samuel K. Young.

Diploma in Public Health (D.P.H.).—Geo. B. Harland, M.B., B.S.Lond., William Mackenzie, M.D.Edin.

The following candidates have passed the second examination for the Degree of Bachelor of Medicine.—Anatomy and Physiology (second class).—Henry Evers, with honours.

Ordinary Pass List.—John F. C. Braine, Cyril C. H. Cuff, Horace G. B. Dove, Ethne Haigh, Reginald A. Hooper, Ah Chit Jap, M.R.C.S., L.R.C.P., Edward Ek Dun Lau, John E. Measham, Claude W. Morris, John D. Proud, Douglas O. Richards, Hugh G. Sparrow, Edgar J. Tyrrell, and Harold Williamson.

Dublin University.

The following honorary degrees are to be conferred on Saturday next, in connection with the Bicentenary Celebrations:—

LL.D.—Sir Thomas Boor Crosby, Lord Mayor of London; Right Hon. Lorcan G. Sherlock, Lord Mayor of Dublin; Sir J. Hawtrey Benson, President, Royal College of Physicians of Ireland; Richard Dancer Purefoy, President of the Royal College of Surgeons in Ireland; William Peterson, Principal and Vice-Chancellor, McGill University, Montreal.

M.D.—Sir Thomas Barlow, Bart., President, Royal College of Physicians, London; Sir John Halliday Croom, Professor of Midwifery, University of Edinburgh; Sir Richman J. Godlee, Bart., President of the Royal College of Surgeon of England; Sir Christopher Nixon, Bart., Vice-Chancellor, National University of Ireland.

D.Sc.—Prof. J. G. Adami, Professor of Pathology and Bacteriology, McGill University, Montreal; Prof. Raphael Blanchard, Professor of Natural History and Parasitology, University of Paris; Prof. Frederick O. Bower, Professor of Botany, University of Glasgow; Prof. Percy F. Frankland, Professor of Chemistry, University of Birmingham; Prof. Ernst Fuchs, Professor of Ophthalmology, University of Vienna; Prof. Karl Ritter von Goebel, Professor of Botany, University of Munich; Prof. A. P. Goubaroff, Professor of Gynæcology, University of Moscow; Prof. Allvar Gullstrand, Professor of Ophthalmology, University of Upsala; Prof. Henr Hartmann, Professor of Operative Surgery, University of Paris; Prof. John N. Langley, Fellow of Trinity College, and Professor of Physiology, University of Cambridge; Sir William Macewan, Regius Professor of Surgery, Glasgow; Prof. Franklin P. Mall, Professor of Anatomy, Johns Hopkins University, Baltimore; Charles J. Martin, Director Lister Institute of Preventive Medicine; Prof. Alexander Maximow, Professor of Histology and Embryology, Imperial Military Academy of Medicine, St. Petersburg; Prof. Hans H. Meyer, Professor of Pharmacology, University of Vienna; Count Carl A. H. Morner, Vice-President, Royal Swedish Academy of Sciences, Stockholm, and Rector of the Caroline Medico-Chirurgical Institute, Stockholm; Prof. Robert Muir, Professor of Pathology, University of Glasgow; Sir William Osler, Bart., Regius Professor of Medicine, Oxford; Prof. Ivan P. Pavlov, Director of the Physiological Department, Imperial Institute for Experimental Medicine, and Emeritus Professor of Physio-

logy, Imperial Academy of Medicine, St. Petersburg; Professor Herman Sahli, Professor of Therapeutics, University of Berne; Prof. Ernest H. Starling, Professor of Physiology, University College, London; Prof. Edgar Fahs Smith, Provost of the University of Pennsylvania; Prof. George D. Thane, Professor of Anatomy, University College, London; Prof. Robert Tigerstedt, Professor of Physiology, University of Helsingfors; Prof. J. Whitridge-Williams, Professor of Obstetrics, Johns Hopkins University, Baltimore.

The following candidates have passed the preliminary scientific examination, Medical School:—

Physics and Chemistry.—Alfred L. Wilson, Eugene McSwiney, Patrick Rocks, William E. Collins, William Dowling, Eric Beatty, Charles Young, Fredk. Murphy, Thomas Sweetnam, Eileen Glenn, Robert A. C. Barrett, Thomas S. Black, Sydney V. Furlong, Roland H. Graham, Thomas Stanton, Carl O'Connor, John A. C. Kidd, and Francois Joubert.

Botany and Zoology.—The following candidates have passed on high marks:—Norman Bor, Thomas J. Chapman, Charles H. Comerford, and Patrick Rocks.

The following candidates have passed the examination:—Patrick Molony, Robert C. Ramsay, Alan Grimby, Eugene McSwiney, Harold McNeile-Dixon, William Fearon, Andries Albertyn, Mortimer McGee-Russell, Francois Joubert, Frederick Murphy, Paul Smith, Robert Stoney, William R. Burns, Thomas J. Lane, James Leahy, David Prentice, Benjamin Merrin, Charles O. Young, Millicent Hamilton-Johnstone, William J. Hamilton, Francis Battersby, Joseph Bird, Edward Lipman, Cyril Littledale, Eileen Smith, Walter Bullen, and Alan Wright.

Intermediate Dental Examination.—The following candidates have passed:—Louis E. Wigoder and Herbert Wright.

The following degrees were conferred last Saturday:—

Honoris Causa.—Doctor in Medicina.—Guilelmus Launcelottus Gubbins (Eques de Ordine Balnei). Baccalaureus in Scientia Dentaria.—Georgius Andreas Yeates.

Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.—Oswaldus Vircentius Burrows, Arturus Chance, Johannes Colgan, Franciscus Stanislaus Crean, Hieronymus Henricus Counihan, Robertus Alexander Flood, Jacobus Herbertus Grove-White, Henricus Percy Harpur, Johannes Timotheus Donal Higgins, Reginaldus Johnson, Robertus Henricus Cummins Lyons, Dorothy Kate Milne, Antonie Chiappini Redelinghuys, Ricardus Eduardus Tottenham, and Georgius Hugh Trayer.

Doctors in Medicina.—Guilelmus Boxwell, Arturus Chance, Franciscus Stanislaus Crean, Frank Crosbie, Townley Garratt Hardman, Georgius Fredricus Columb Healey, Carlisle Kelly, Matthaeus M'Knight, Mauricius Sydney Moore, Robertus Walpole Murphy, Henricus Jocelyn Smyly, Bethel Solomons.

Trinity College, Dublin.

THE following candidates have passed the intermediate medical examination, Part II., Trinity Term, 1912:—Joseph A. Quinn, Philip W. McKeag, Robert J. B. Madden, Frederick C. Fleming, Thomas W. G. Johnson, Walter J. Ronan, Robert L. Vance, William O. Tobias, Richard W. Acheson, William L. Bates, Francis A. L'Estrange, and Edwin Boyers.

Conjoint Examinations in Ireland.

THE following candidates have passed the Preliminary examination of the Royal College of Physicians and the Royal College of Surgeons, June, 1912:—F. J. Bowers, T. J. Clune, J. Cusack, J. L. Farnon, J. Geraghty, F. G. Hall, V. Hawkins, P. Hegarty, J. F. Holmes, L. B. Leonard, M. O'Donnell, M. P. O'Meara, W. Robinson, A. Y. Sloane, R. J. Tate, and H. C. Williamson.

Third professional examination, June, 1912.—R. J. Brookes (with honours), R. A. Austin, H. A. S. Deane, G. S. Douglas, J. Lanigan, F. B. McTavish, J. J. O'Connell, H. O'Donoghue, J. J. Reynolds, M. Shipsey and F. M. Taylor.

NOTICES TO CORRESPONDENTS, &c.

✍ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, 4s.; Half Page, £2 10s.; Quarter Page, £1 6s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

L. S. A. (Herts).—"Urogenin" is a double salt of theobromin and hippurate of lithium, used as a diuretic, having an action similar to digitalis. "Letargin" is a local anaesthetic composed of Ext. Hamamelis, Novocain, Sod. Chlorat., and Thymol, together with one drop of a one per 1,000 solution of Suprarenin Hydrochloride.

"CATTIONS ONE" has no need to wait until secondary symptoms arise, for the diagnosis can be made at once by simply scraping the surface of the sore and examining under the microscope by means of the dark ground illumination method. The identification of the spirocheta pallida can readily be determined after a little practice.

A. S. G. (Aix-les-Bains).—Yes, to Prof. Bettmann, at Heidelberg.

CANCER.

SUGGESTED on reading leading article in MEDICAL PRESS, June 19th. (The diagnosis of Cancer was said to depend on the recognition of "Giant Cells" in the blood or tissues by the microscope.)

"The very many treatments tried,
Have one by one been cast aside,
Regretfully we now must tell,
All (so-called) cures (?) a giant 'cell.'"

A. D.

Dr. P. C. E. (Hants).—The so-called "phossy jaw" is now happily, a thing of the past owing to the prohibition of the use of white phosphorus for making matches. It is universally conceded that phosphorus sesquisulphide is free from the risks accompanying the employment of the ordinary phosphorus.

M.B. Edin. (Somerset).—We are informed upon high authority that you would be well advised to sign the complementary pledge, the last clause of which might be slightly modified to meet the conditions of the neighbourhood and the class of patient usually seen at the institution in question.

M.R.C.S. (Southend).—There is no ethical reason whatever against a medical man identifying himself with municipal life. On the contrary, the presence of a medical member of a borough council may be of the greatest use in assisting his lay colleagues towards correct decisions in all matters respecting the sanitation and health of the district.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 3RD.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Duncan). 5.30 p.m.: Eye Operations (Mr. Brooks).

THURSDAY, JULY 4TH.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (1, Wimpole Street, W.).—8 p.m.: Short Communications by Dr. Blair Bell and Dr. Tenison Collins. 9 p.m.: The President (Dr. Amand Routh) will give a Review of the Work of the Session. Votes of thanks to the retiring Officers and Members of Council.

Appointments.

BANTING, C., M.D., B.S.Lond., F.R.C.S.Eng., Clinical Assistant in the Ear and Throat Department at University College Hospital.

BALDWIN, ASLETT, F.R.C.S.Eng., Surgeon to St. Mark's Hospital.

BRERCLIFFE, R., M.B., Ch.B.Vict., Assistant Director of the Clinical Laboratory at the Manchester Royal Infirmary.

COURTS, A. C. S., M.B., B.S.Lond., House Surgeon at University College Hospital.

DARWALL SMITH, G. F., M.B., B.Ch.Oxon., F.R.C.S.Eng., Assistant Obstetric Physician to St. George's Hospital.

FENWICK, STEPHEN, F.R.C.S.Eng., Assistant Surgeon to the Out-patient Department at Charing Cross Hospital.

GOW, JOHN, M.B., Ch.B.Vict., Accident Room House Surgeon at the Manchester Royal Infirmary.

HENDERSON, A. A., M.R.C.S., L.R.C.P.Lond., Obstetric Assistant at University College Hospital.

LEITCH, E. B., M.D.Cantab., M.R.C.P.Lond., Assistant Medical Officer at the Manchester Royal Infirmary.

LOCKYER, CUTHBERT, M.D., B.S.Lond., M.R.C.P.Lond., F.R.C.S.Eng., Assistant Obstetric Physician to Charing Cross Hospital.

MELLAND, C. H., M.D.Cantab., M.R.C.P.Lond., Assistant Medical Officer at the Manchester Royal Infirmary.

SELLERS, WILLIAM, M.D.Lond., D.P.H., Professor of Forensic Medicine in the University of Manchester.

SHAW, CECIL E., M.D., M.S.R.U.I., Lecturer in Ophthalmology and Otology in the Queen's University of Belfast.

SYMMERS, W. ST. C., M.B., M.S.Aberd., Lecturer in Medical Jurisprudence at the Queen's University of Belfast.

Vacancies.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician. Salary (for six months) £30, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.).

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Salary (for six months) £30, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.).

Manchester University.—Junior Demonstrator in Physiology. Salary £100 per annum. Application to the Registrar.

Essex and Colchester Asylum, Brentwood.—Assistant Medical Officer. Salary £160 per annum, with board, etc. Applications to the Medical Superintendent.

Great Yarmouth Hospital.—House Surgeon, Salary £100 per annum, with board, lodging, and washing. Richard F. E. Ferrier, Honorary Secretary, 33, Hall Plain, Great Yarmouth.

Gravesend Hospital.—House Surgeon. Salary £100 per annum, with board and residence. Applications to W. Pearson, Secretary.

Teignmouth Hospital, S. Devon.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to the Honorary Secretary.

Royal Asylum, Morningside, Edinburgh.—Assistant Physician. Salary £150 per annum, with board, lodging, etc. Applications to Physician-Superintendent.

Carmarthen Joint Counties Asylum, South Wales.—Second Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Births.

BONHOTE HENDERSON.—On June 26th, at Salisbury, the wife (Katherine Smijth-Windham) of T. Bonhôte Henderson, M.A., M.B., Oxon., F.R.C.S.Eng., of a daughter.

FAIRBANK.—On June 26th, at 84, Harley Street, W., the wife of H. A. T. Fairbank, M.S., F.R.C.S., of a son.

HATFIELD.—On June 27th, at York House, Park Road, Forest Hill, the wife of Harry F. Hatfield, M.R.C.S., of a son.

LETCHWORTH.—On June 29th, at 68, Claremont Road, Surbiton, the wife of T. W. Letchworth, M.B., F.R.C.S., of a son.

TOD.—On July 1st, at 11, Upper Wimpole Street, W., the wife of Hunter F. Tod, of a daughter.

TOOTH.—On June 26th, at 54, Harley Street, W., the wife of Howard H. Tooth, M.D., C.M.G., of a daughter.

Marriages.

LANDMAN—LIGHTMAN.—On June 26th, at the Belgrave Street Synagogue, Leeds, Julian Landman, M.D., of Highlands, 583, Finchley Road, London, N.W., eldest son of Mr. and Mrs. L. Landman, of 11, Brunswick Street, Leeds, to Lily, second daughter of Victor Lightman, Esq., J.P., and Mrs. Lightman, of the Towers, Roundhay, Leeds.

MURRAY—BLAKE.—On June 26th, at All Saints' Church, Ecclesall, Sheffield, Charles Grahame Murray, M.D., son of the late Alleyne Pilgrim Murray, and of Mrs. Murray, of Barbadoes, to Margaret Elizabeth, fourth daughter of the late Major Blake, J.P., D.L., and of Mrs. Blake, Mylnhurst, Sheffield.

Deaths.

BOTTRELL.—On June 23rd, at Eden House, St. Ives, Cornwall, James Francis Henry Bottrell, M.R.C.S.E., L.S.A., etc., aged 57 years, late of Villarrica, Paraguay, S. America.

MURRELL.—On June 28th, William Murrell, M.D., F.R.O.P., Senior Physician to Westminster Hospital, of 17, Welbeck Street, W.

SCOTT.—On June 26th, at Rumbold House, Ilkley, Thomas Scott, M.D.

THE MEDICAL PRESS AND CIRCULAR

Vol. CXLV.

WEDNESDAY, JULY 10, 1912.

No. 2.

NOTES AND COMMENTS.

Insurance Act in Scotland.

THE annual meeting of the Edinburgh Branch of the British Medical Association, held last week, was marked by unanimous resolutions that must be viewed with apprehension by those hopeful of effective union in the ranks of Scottish medical men. The first resolutions ran:— "That the meeting express its extreme disapprobation of the action of Dr. Matheson Cullen, in accepting one of the paid medical officerships for Scotland under the National Insurance Act. (2) That the meeting express its strong disapproval of the action of Sir James Russell in agreeing to act on the Provisional Local Insurance Committee as medical representative at the Town Council of Edinburgh." The acceptance of both appointments, it is stated, is in direct antagonism to the declared and deliberate policy of the British Medical Association and the Scottish Medical Insurance Council. The branch think it right that the public should be informed that on account of the unfortunate methods of the Government the best men in the profession decline to serve under the Act, unless their reasonable demands are conceded. The unhappy "betrayal" at headquarters in London appears to be bearing bitter fruit in Scotland, but it may be confidently anticipated that those who will actually go the length of accepting posts under the Act, in spite of the cardinal points of protest, will be in a fractional and futile minority.

A Second Resolution.

THE Edinburgh meeting, however, expressed a further unanimous disapproval, the meaning of which we confess we are at a loss to understand. They thus condemned the action of Dr. Norman Walker, Direct Representative of Scotland in the General Medical Council, in refusing to place his resignation as a member of the Scottish Advisory Committee in the hands of the Scottish Medical Insurance Council, to be used if and when found to be wise and expedient, and to call upon him to explain to the profession his reason for such decision on his part. That a satisfactory explanation will be forthcoming it is hardly possible to doubt, in view of the long services and proved loyalty of Dr. Norman Walker to the profession. There must be some strong motive to induce him to take the position of being the only one of the eleven medical members of the Scottish Advisory Committee who has refused to give an undertaking that he will resign his position on the Advisory Committee if called upon to do so by the Scottish Medical Insurance Council. In any case, it would be impossible to doubt the straightforwardness and sincerity of Dr. Walker's motives, or that his refusal was prompted by any falling away from the spirit of loyalty which has placed him in his present representative position.

The Inner Mind of the Profession.

THAT genial humorist, Mr. Spencer Leigh Hughes, who for many years has furnished society with a perennial fount of wit and wisdom under the *nom de plume* of "Sub Rosa," has turned the searchlight of his analytic brain upon the medical profession. Simple as the problem may seem, it is in reality an extremely difficult thing to define the politics, the unwritten laws, the orthodoxy, the inner mind—call it what you will—of the medical world. Mr. Lloyd George turned to the British Medical Association and to a few political wire-pullers, and thought that after the little swim in surface waters he had gauged professional opinion to a nicety, but he has since found out his mistake. The motif of medical collectivism is not to be found in corporate bodies, which are for the most part in the hands of interested wire-pullers, but in the main ranks of the medical men of the Kingdom. How they are to be organised and taught to reduce their views to effective expression is the problem that now occupies the immediate foreground of the professional horizon. On that point no satisfying information can be at present offered either to Mr. Lloyd George or to the gifted writer, "Sub Rosa." At the same time, it is a comparatively easy enough matter to point out where they go astray in dealing with medical affairs.

Medicine not an exact Science.

NOR long ago, "Sub Rosa" wrote an interesting column upon a by-gone stage of medical gropings after truth. He mentioned the fact that sundry gross abominations were administered to the Charleses, father and son, and apparently sought to fix the stigma of the ignorance and credulity of that period upon a sort of mystic folly bred in the bone, so to speak, of the medical art. As a matter of fact, there was plenty of sound therapeutic wisdom and an abundance of good remedies known in the days of the Stuarts. The error of "Sub Rosa" seems to lie in his determination to regard modern medicine as an exact science. In point of fact, it is nothing of the kind. Medical knowledge is still like a tiny rivulet meandering through a vast unknown meadow, although, happily, with the process of centuries its banks are visibly and rapidly widening. However, there is one consolation to medical workers who are within the ranks of the regular army, to wit, that their practice represents the best available at any given time to human knowledge. Mr. Hughes is right when he points out that a great man like Robert Boyle (*circiter* 1650) advocated foolish abominations. Well, futilities of this kind have never been accepted permanently by the medical profession,

and no great truth but has sooner or later been accepted in the medical world. That is, perhaps, after all, the most illuminating criticism that can be offered to lay writers upon medical philosophy.

"Queen Alexandra Day" has come and gone in London, and another graceful anniversary has been added to the social calendar. A great deal of money has been collected for the benefit of the voluntary medical charities, and there is much to be said in favour of a movement which calls attention to the most beneficent and practical forms of modern philanthropy. At the same time, it may be well to ask on what principles the distribution of the money thus collected will be made. A correspondent has put the matter in a nutshell. Will the small and special hospitals be included in the grants, or will the Alexandra follow the example of the other great metropolitan funds (except the Saturday) and ignore the lesser institutions? As the money has come from the people it is only fair that part of it should go to the smaller organisations which every year provide so large an aggregate amount of skilled medical relief for the people of London. It is to be hoped that those responsible for the administration of the Alexandra Day Fund will insist on an equitable all-round distribution of grants.

LEADING ARTICLES.

THE BICENTENARY CELEBRATIONS AT TRINITY COLLEGE, DUBLIN.

THE festival held last week in Dublin was one of world-wide interest. That this was fully recognised was shown by the remarkable concourse of learned men who flocked from all parts of the world to do honour to a famous school of science. Distant Siberia, Japan, and Winnipeg sent delegations, who sat down with those from Belfast, from Cork, from Galway, and from all the universities and learned bodies of the Kingdom. The common message was one of congratulation on the past, and encouragement for the future. All were ready to recognise the achievements of the Dublin school in the past—in anatomy, in midwifery, in medicine, in surgery. All were equally ready to have confidence for the future. The concourse of learned men from all over the world on such an occasion as this is of help to the progress of science, though not a word be interchanged dealing directly with scientific matters. To younger men starting in their career, it is an inspiration to have merely seen some of the great ones of the earth, whose names are household words in the halls of science. To earnest workers the meeting with others working on the same or parallel lines is a help and an encouragement. But a festival such as that in Dublin teaches to the world a remarkable lesson of the community, the solidarity of the republic of science. It is a republic that knows no frontiers, that has no provincialism. All international jealousies are lost therein, all political differences disappear. The festival was worthy of the occasion, not only from the number and eminence of the distinguished men who travelled long distances to accept the invitation

of the University to be present, but in the dignity of the programme arranged by their hosts. The noble buildings of Trinity College, the fine stretches of green sward, looked their best in the glorious weather with which the festival was favoured. It is doubtful whether any University College in the world is more fortunate in its site than Trinity College. In the heart of a great city, it has space such as might form a good-sized demesne for a country house. There is privacy in its gardens greater than in any in Oxford or Cambridge; there are vistas of trees and parks which almost delude one into believing himself in a quiet country-side. Not for twenty years—since the Festival of the Tercentenary of its Foundation—did the old College look so gay as last week. We give a detailed account of the various ceremonies of the festival elsewhere. Garden parties in beautiful surroundings, dinners in noble halls, academic functions of due solemnity, form a picture none who took part therein can readily forget. It was, moreover, a happy thought of the City of Dublin and its Lord Mayor to take a proper place in the celebrations. The city is the greatest benefactor in the history of the College. The Lord Mayor showed a constant interest in the celebrations, not only by his presence at many of the functions, but by his kindly loan of the dining-hall of the Mansion House for the Graduates' Dinner. It was pleasant, too, to find that among the warmest congratulations to the ancient College were those from her younger sisters, whom some have been so foolish as to regard as rivals.

THE ANNUAL ELECTION AT THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

THE annual election of members to the Council of the Royal College of Surgeons, England, took place on the 4th instant. The occasion was somewhat noteworthy by reason of the number of vacancies which had been declared. Only rarely does it happen that the electorate is called upon to vote for four candidates, but this was the number whose election was necessary to fill the vacant seats. Naturally the opportunity was regarded as a favourable one among those desirous of the fame and honour generally supposed to belong to the membership of the Council of the College, and consequently a full list of candidates was presented. Three of the candidates were competing for re-election, namely Sir Frederic Eve, Sir Anthony Bowlby, and Mr. Gilbert Barling, of Birmingham; and the list was completed with four others. Out of this goodly list it is of interest to note the medical schools represented by the various candidates. Two of these latter were representatives of St. Bartholomew's, two of the provincial schools (Leeds and Birmingham), and one each of the London, St. Mary's and Guy's respectively. The successful candidates, declared by the President after the poll, were Sir Frederic Eve, Sir Anthony Bowlby, Mr. D'Arcy Power, and Sir Berkeley G. A. Moynihan. Thus Mr. Gilbert Barling failed

to secure re-election, being seven votes behind the lowest successful candidate upon the list. The Council as at present constituted contains no fewer than five members of the surgical staff of St. Bartholomew's Hospital; of the Guy's staff there are four; of Middlesex, three; of St. Thomas's, two; of the London, two; of University College, two; and of St. Mary's, King's, St. George's, Bristol, Birmingham and Leeds, one each. The excessive proportionate representation of the St. Bartholomew's school casts, perhaps, some suspicion of unfairness when considered in respect to the other schools, and especially those in the provinces which are not represented upon the Council. But this disproportionate representation has practically always existed, so far as St. Bartholomew's is concerned. Nor is the explanation far to seek. The school is one of the largest in the metropolis; its *alumni* loyally support their teachers, and this loyalty is so maintained and practised, that almost upon every occasion, a member of the staff of the Hospital is assured of his election. Among the smaller medical schools, such a measure of support is naturally impossible—and thus the Council is apt to assume the position of a "close borough," confined mainly to the staff of the larger schools, to the exclusion of many representative surgeons by whom the honour would be filled no less worthily. It would, therefore, seem that some reform is desirable in this matter. Why should, say, the senior surgeon of a smaller hospital be debarred from successfully obtaining a seat on the Council because of the swamping of his support by the large schools? Membership of the Council in the present day does not imply the expression of any special political convictions; it is merely an honour, personal to the surgeon who holds it, with the additional attraction that it may lead to the Presidency of the College, a position which is rightly coveted. With regard, however, to the election of the President, a matter which rests entirely and exclusively in the hands of the Council itself, the Council has ever shown itself jealous of the dignity of the honour to which it has the power to dispose. To gain the Blue Riband of the surgical profession in this country is naturally an ambition to which the members of the Council aspire. Nevertheless, it is generally known that no friendships nor favour will secure that position for any member of the Council; hence disappointments in this regard have not infrequently occurred. The election is untainted by any personal considerations. The choice always falls upon the most representative surgeon who, for the time being, has a seat on the Council. Usually, of course, the surgeon is one who practises general surgery, but the rule is not adamant, as was shown in the case of Sir John Tweedy—the ophthalmic surgeon—who held the post for three successive years. Still, however, while we cannot point to any evil arising from the disproportionate representation of the medical schools on the Council, we believe that a useful reform would be to limit—if only by the time-

honoured expedient of an unwritten law—the representation of each school. That would permit of the wider distribution of an honour from which many surgeons feel that they are excluded, by virtue of the fact that they represent the smaller medical schools.

CURRENT TOPICS.

The Economics of the National Insurance Act.

IN our Correspondence columns we print an important letter from Dr. Angus Macphee, of Glasgow, who deals at length with the economics of the Act which occupies so much of the medical horizon. The moral which he enforces is that Mr. Lloyd George will have ample funds wherewith to pay the 8s. 6d. grant to medical men, and that it will not only be suicidal to accept any less sum, but will also constitute a disgraceful and disloyal act on the part of any practitioner who refuses to join his professional brethren in insisting upon that fair and reasonable fee. The main argument appears to be, that if friendly societies with 5,000,000 members contributing 7d. per week, pay management expenses, grant 4s. per member for doctor, and save, say, £30,000,000, how much more can the Insurance Act, with 15,000,000 members, contributing 9d. per week, and with only part of management expenses to pay, satisfy the medical demand of 8s. 6d. per head. The State, surely, does not want to make money at the expense of a poor profession like that of medicine. Those interested in the matter will do well to study the original letter of our correspondent. The Act comes into force within a few days, and it seems an extraordinary position that responsible politicians have still to be enlightened on the medical economics of the question. It is indeed time the public medical service scheme were safely launched.

The Neglect of the Home Spas.

THE failure to appreciate aright home-grown industries and native resources constitutes one of those modern tendencies of which we have but little occasion to be proud. For some time past it has been considered fashionable to decry the average British spa, to magnify its alleged shortcomings, and to hold up the Continental watering-place as the model of health resorts for all time. The medical profession is, to some extent, responsible for this state of affairs. Is it not too often the case that a gouty, dyspeptic, or rheumatic patient is rushed off to one of the popular Continental spas to undergo some cure or other, without even so much as a thought of the claims of one of our own institutions? British balneologists are, naturally, somewhat indignant at this neglect of the home spas by the average practitioner, for it must be admitted by those who have any knowledge of the subject that hydrotherapy in all its aspects has been as scientifically developed in this country as anywhere in the world, though its evolution has taken place a little later. Foreign health resorts have had, therefore, a good start, but they are being rapidly overtaken by English spas. As Dr.

Charles Gibson remarked the other day at the annual meeting of the Yorkshire Branch of the British Medical Association, no European health resort can equal Harrogate for the variety and richness of the mineral constituents of its eighty springs. If this fact were more widely known upon the Continent we should have hosts of foreign visitors coming over to take the cures in this beautiful Yorkshire watering-place. There are many other famous springs and baths, such as those of Bath and Buxton, which are the pride and glory of hydrotherapeutists throughout the country.

The Dangers of Primitive Scavenging Methods.

WE have, on several previous occasions, called attention to the grave risks to health associated with the collection of house refuse as ordinarily carried out by means of the open dustcart. This archaic vehicle, with its still more ancient-looking baskets, is still to be seen even in fashionable West-End thoroughfares, scattering its contents broadcast on hapless passers-by with every gust of wind. A recent letter from the pen of Mr. Harrison Cripps, published in the *Daily Mail*, should awaken public attention in the matter, which should not be allowed to degenerate into the usual aimless correspondence upon health matters that is wont to appear in the daily Press at or about this season of the year. Clearly, many of the present methods of scavenging are wholly at variance with modern sanitary ideas, and the sooner a more hygienic system is adopted, the better for the health of the public. The first thing to do is to abolish absolutely the old-fashioned dustcart with all its grimy appurtenances. The galvanised iron receptacles now commonly supplied to every household should simply be collected and emptied at the place of sorting, a clean and empty bin being left in its place. Presumably, the extra expense and trouble that would doubtless be connected with this system would be matters of greater consideration, even by so-called enlightened borough councils, than the health of the community. Street sweeping and scavenging are of little use if one great source of dust, with all its contained disease-germs, is still allowed to remain unremoved.

Inebriety in Fiction.

It has become to be almost a truism that when novel writers indulge in descriptions of diseases, their symptoms and treatment, they often become hopelessly entangled. In intending to pourtray the characteristics of medical life and practice they again often leave the critical reader in a state of bewilderment. Unless the author be himself a medical man, or unless the collaboration of the latter be sought on professional details, it is seldom, indeed, that glaring mistakes of this kind will not be found somewhere within the pages of even the most up-to-date work of fiction. With regard to alcoholism, Mr. Guy Thorne, author of "The Drunkard" (a), while acknowledging the changed attitude of novel writers on the whole towards inebriety during the last thirty or forty years, finds that the psychological aspect of this problem has been almost entirely neglected. Neither the master-

ful realism of a Zola nor the glowing delineation of a Besant really deals with the mental state of the chronic inebriate, nor reveals the innermost workings of his morbid brain. What is urgently wanted in these days of popular fiction is the novel that discusses these conditions sanely, accurately, and, above all, written in an attractive style. This may be regarded, perhaps, as ideal, but it is the only way in which medical teaching and influence can be reinforced by fiction.

Red Cross Work in China.

IT is always gratifying to receive praise for work well done, and when this recognition comes from foreign sources for medical services rendered, it is worth recording in the pages of a medical journal. In the course of a letter from Dr. S. Y. Ho, Surgeon-General to the Northern Forces of the Chinese Republic, sent from the War Office at Peking to the London Missionary Society thanking that Society for its efficient Red Cross work during the recent revolution, the following passages occur:—"We must thank you for your valuable aid and benevolent work done to our poor refugees and wounded soldiers from the outbreak of the revolution in Hankow till the end. Over one-third of our total wounded Northern troops were admitted to your hospital and treated under your care. Many lives were saved, and about 90 per cent. left with complete recovery. The necessity and value of prompt and efficient first aid in injuries needs no comment, as the fate of an injured person depends upon the acts of the person into whose hands he first falls. By the prompt application of first-aid dressings and proper treatment, the loss of life and limbs has been reduced to the lowest ratio in the whole history of warfare." This praise addressed to Dr. Fowler necessarily includes the trained Chinese Christian helpers who gave him much efficient assistance, and it is also a feather in the cap of the medical staff of the London Missionary Society.

The Passing of the Apothecary.

MANY changes have taken place in the mode of evolution of the medical practitioner, even in the course of a single generation. It has become customary to allude to these gracefully and apologetically in the course of public addresses to medical students who are apt to plume themselves in consequence as being so much better fellows than their predecessors of the Victorian age. To one of these changes Lord Rosebery referred last week in the course of a speech delivered at the London Hospital upon the occasion of the annual prize distribution, namely, the practical extinction of the apothecary of fifty years ago. This familiar individual of the period was reckoned to be a "great medicine-man," as the Indians would call him, in the most literal sense of the word, for he lived among drugs, and would compound them himself daily. The abolition of the art of dispensing as part and parcel of the routine work of so many medical men, has, no doubt, reacted favourably upon the practice of medicine as a whole, but it has its disadvantage of depriving the practitioner of that intimate knowledge of pharmacy which seems to form a connecting-link between himself and the patient. There is now scarcely any need for a medical man to be

(a) *British Journal of Inebriety*, July, 1912.

acquainted with even the rudiments of dispensing, unless he intend to practise in a very remote country district, for his incompatibles, should he be guilty of prescribing such, and even his doses will be checked by his ever-watchful dispenser. The medical man who makes up his own medicines at least knows the contents of each bottle, and he cannot help seeing their colour and general appearance. The advantage of this is obvious when he is asked by Mrs. Jones for some more of the "splendid brown medicine she had about nine months ago." If, as Lord Rosebery implied, the apothecary as a type has gone in name, his spirit is not yet dead, nor, we believe, is it ever likely to be.

Surgical Auto-Operation.

THE annals of surgery record several striking instances of surgeons performing serious operations upon their own bodies. Such a proceeding could be humanly possible only under the special conditions provided by the modern method of producing local anaesthesia. The most recent incident of the kind comes from Toulon, where Admiralty Surgeon Regnault is reported to have performed an operation upon himself for inguinal hernia on the left side at the Hospital of St. Maudrie. Propped up by cushions on the operating table, he is described as administering to himself an injection of cocaine, after which he proceeded calmly to carry out the necessary surgical procedure under the supervision of his colleagues, Drs. Gastinal and Dufour, assisted by several students. The operation is stated to have taken an hour and a-quarter, and during its performance several photographs were taken. The distinguished surgeon is now convalescent. An incident of this kind demonstrates the power of inflexible will and the marvellous confidence which inspires the hand of the experienced surgeon. Under some circumstances it might be necessary or desirable for a surgeon to undertake the serious responsibility involved in performing a major operation upon his own *corpus vile*, but where skilled surgical aid is obtainable, the practice is not to be commended, even though the world be enriched with moving pictures of drama showing human nature in one of the highest conceivable positions of acquired self-control and resolute bravery.

PERSONAL.

H.R.H. PRINCESS CHRISTIAN opened, last week, the Cottage Hospital, which has been erected as a memorial to King Edward at Haywards Heath.

THE DUKE OF DEVONSHIRE opened at Buxton, last week, the reconstructed Pump Room, which contains the famous St. Ann's Well.

MR. ROBERT DAVIES-COLLEY, M.A., M.C.Cantab., F.R.C.S., has been appointed an assistant Surgeon to Guy's Hospital.

DR. BARCLAY-SMITH has been reappointed University Lecturer in Advanced Human Anatomy in the University of Cambridge.

DR. HILDRED B. CARLILL, M.A., M.D., M.R.C.P., has been elected Medical Registrar and Tutor at the Westminster Hospital.

THE appointment of Dr. R. Henslowe Wellington as Deputy-Coroner for the South-Western District of London has been sanctioned by the chairman of the Cottage Council.

DR. W. E. ROBINSON, M.D., B.Ch.Oxon., has been appointed Visiting Anaesthetist to the Royal Waterloo Hospital for Children and Women.

MR. F. J. STEWARD, M.S., F.R.C.S., Senior Assistant Surgeon to Guy's Hospital, has been appointed to the full staff.

DR. C. GIBSON, of Harrogate, has been elected President of the Yorkshire Branch of the British Medical Association for the ensuing year.

DR. BASIL KILVINGTON has been appointed an Examiner in Surgery in the University of Melbourne, in the place of the late Mr. Rennie.

MR. S. W. DAW, M.B., B.S., F.R.C.S., has been appointed Surgical Registrar at the General Infirmary, Leeds, and Surgical Tutor, Leeds University.

MR. C. J. SYMONDS, M.D., M.S., F.R.C.S., has been appointed Consulting Surgeon to Guy's Hospital, upon his retirement from the post of Senior Surgeon thereto.

DR. HUGH KERR ANDERSON, F.R.S., Fellow of Gonville and Caius College, Cambridge, has been elected to the Mastership thereof in succession to the late Rev. E. S. Roberts.

DR. E. U. BARTHOLOMEW has been awarded the Chesterfield Silver Medal in Dermatology for 1912, after examination at St. John's Hospital for Diseases of the Skin.

AMONG the recipients of the honorary degree of LL.D. of the University of Edinburgh last week were Sir James Porter, C.B.; Professor J. T. Cash, F.R.S., of Aberdeen; and Professor W. C. McIntosh, F.R.S., of St. Andrews.

DR. JAMES MARTIN BEATTIE, of Sheffield University, has been recommended for appointment as Bacteriologist to the City of Liverpool by the committees of the various public bodies most intimately concerned in bacteriological work.

MR. ARTHUR ERNEST HAYWARD, M.R.C.S., L.S.A., of Teignmouth, was presented the other day with a handsome ivory and ebony walking-stick by the poor of the district upon the occasion of his leaving the neighbourhood to go to Australia.

PROFESSOR CHARLES CHILTON, M.A., D.Sc., M.B., C.M., Professor of Biology and Palaeontology at Canterbury College, University of New Zealand, has recently been the recipient of the honorary degree of LL.D. of the University of Aberdeen.

DR. WILLIAM ROBINSON, founder and chairman of the Society for the Prevention and Cure of Consumption in the County of Durham, was recently the recipient of a handsome silver salver in recognition of his valuable services in connection with this department of preventive medicine.

At a special meeting of the Royal College of Surgeons of Ireland on Thursday last the honorary Fellowship of the College was conferred on Mr. Robert Jones, F.R.C.S., Liverpool; Sir William MacEwen, Glasgow; Sir Henry Morris, F.R.C.S., London; Sir Lancelot Gubbins, Director-General, Army Medical Service; and Professor Irving Cameron, M.D., Toronto.

SURGEON LIEUTENANT-COLONEL WILLIAM TAYLOR, M.D., L.R.C.P., M.R.C.S., L.S.A., J.P. for Glamorganshire and Cardiff, a former Mayor of Cardiff, lately president of the South Wales and Monmouthshire branch of the British Medical Association and of the Cardiff Medical Society, and consulting physician to the Cardiff Infirmary, who died off the coast of Greece on May 8th, aged 82, left estate of the gross value of £55,519, of which £20,000 is net personality.

A CLINICAL LECTURE

ON

THE TREATMENT OF DYSPEPSIA. (a)

By W. H. WILLCOX, M.D., F.R.C.P.,

Physician to Out-Patients, St. Mary's Hospital, Paddington.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE term Dyspepsia means, according to derivation, difficulty of digestion, and it is synonymous with the common term "Indigestion." In considering the treatment of dyspepsia, it is proposed to consider the treatment of those cases where the most common symptoms are such as would reasonably be represented by the term Dyspepsia or Indigestion, and where on account of the symptoms of supposed dyspepsia or indigestion the patient seeks medical advice.

It will be generally admitted that the symptoms included under the term dyspepsia or indigestion are of exceedingly common occurrence, and perhaps there is no condition for which medical treatment is more often required.

Before a case of dyspepsia can be successfully treated, it is essential that the ætiological factors should be thoroughly understood, since the treatment of the patient will depend entirely on the pathological condition which has given rise to this group of symptoms.

Dyspepsia, or indigestion, is the prominent symptom, or group of symptoms, in a very large number of diseases, and unless this fact is clearly borne in mind, mistakes—or, rather, omissions—in diagnosis are bound to be made.

In every case of dyspepsia it must be remembered that the symptoms of which the patient complains are due to some pathological cause, and it is this primary ætiological condition which demands treatment. It is the cause, and not the symptoms, which must be treated.

The following table gives a summary of the principal causes of dyspepsia or indigestion:—

I. LOCAL PATHOLOGICAL CONDITIONS OF THE ALIMENTARY TRACT.

Such as Abnormal conditions of the mouth, stomatitis, pyorrhœa alveolaris, etc. Abnormal conditions of the pharynx, naso-pharynx and œsophagus.

Dietetic indiscretions, Abnormal conditions of the stomach, such as gastritis (either acute, sub-acute, or chronic), dilatation of the stomach, gastroptosis, gastric and pyloric ulcer, carcinoma, hypertrophic pyloric stenosis.

Abnormal conditions of the intestinal tract, such as enteritis or colitis (whether catarrhal or due to a specific infection).

Growth of the Bowel, Inflammatory conditions of the bowel, such as appendicitis, etc.

Enteroptosis, Any cause giving rise to intestinal obstruction, such as hernia (whether external or internal), volvulus, intussusception, kink of bowel from adhesions, Meckel's diverticulum, etc.

Abnormal Conditions of the Peritoneum, such as acute, sub-acute, or chronic peritonitis, adhesive peritonitis, growths involving the peritoneum, etc. Abnormal conditions of the liver, gall-bladder, spleen, pancreas, Moveable kidney, etc.

II. BACTERIAL INFECTIONS GIVING RISE TO TOXÆMIA.—One of the common symptoms of these

conditions is dyspepsia. Examples are the dyspepsia of early phthisis, the dyspepsia which is often the onset of the various infectious diseases; the dyspepsia associated with the septicæmia or pyæmia of various bacterial infections.

III. AUTO-INTOXICATION.—In many diseases, owing to various reasons such as defective excretion, or defective production of internal secretion, or defective metabolic processes of various kinds poisons accumulate in the body and give rise to an auto-intoxication or toxæmia. The prominent symptom in many of these cases of auto-intoxication is dyspepsia. Examples are:—Renal disease, with uræmic dyspepsia; Addison's disease; gout; diabetes, where dyspepsia is often the early symptom of threatening coma; acute yellow atrophy of the liver; recurrent vomiting of children; acid intoxication from various causes.

IV. TOXIC CAUSES DUE TO CHEMICAL POISON OF VARIOUS KINDS, *e.g.*, Corrosive and Irritant poisons, also poisons which, by their action after absorption, produce symptoms of dyspepsia without causing any definite local effect. This includes an enormous number of substances. Examples are:—Alcohol; Lead, copper, zinc, and other metallic poisons to which industrial workers are specially liable; Tobacco; Anæsthetics generally and their after-effects, including delayed chloroform poisoning. Drugs derived from Benzene and its compounds, such as salicylic acid, aceto-salicylic acid, acetanilide, etc. This group includes many of the drugs which are so commonly taken in tabloid form.

Gaseous poisons, such as the atmospheric impurities of over-crowded rooms; impurities arising from escapes of coal gas, or from the leakage of the products of combustion, into the air of rooms owing to the use of gas fires or stoves or heating apparatus of various kinds where the products of combustion are not carried off; escapes of sewer gas due to defective sanitation, etc.

V. NERVOUS CAUSES—*e.g.*, Reflex irritation of various kinds may give rise to dyspepsia, Cerebral tumour and intra-cranial lesions generally, such as meningitis, abscess, etc.; Migraine; Gastric crises associated with tabes dorsalis, general paralysis and other nerve diseases; Gastric crises of angio-neurotic œdema.

VI. DISEASES OF THE CIRCULATORY AND RESPIRATORY SYSTEMS.—These are frequently associated with dyspepsia, owing to the venous congestion of the abdominal organs present, and also because not infrequently a condition of acute dilatation of the stomach may arise in cases of severe morbus cordis. Then again the vascular changes of arteriosclerosis and resulting high blood-pressure are often associated with dyspepsia.

VII. BLOOD DISEASES—*e.g.*, Chlorosis, Pernicious anæmia, Leukæmia, Splenic anæmia (a special type of which is Banti's disease), Lymphadenoma. In these conditions one of the commonest of the early symptoms for which medical advice is sought is dyspepsia.

VIII.—PREGNANCY.—In the first two or three

(a) Lecture delivered at the Medical Graduates' College and Polyclinic, June 3rd, 1912.

months severe dyspeptic symptoms are common, and these symptoms sometimes persist so that the vomiting of pregnancy may become a serious complication, leading to the necessity of surgical treatment. Pregnancy also often causes nephritis, with its associated uræmic dyspepsia.

IX. FUNCTIONAL DYSPEPSIA.—Here the symptoms are due to neurosis, and have no gross organic lesion to account for them.

EXAMINATION OF THE PATIENT.

A review of the above list of the important causes of dyspepsia makes it evident that before attempting to treat a case a systematic and careful examination is necessary in order that the treatment may be carried out on ætiological lines.

Thus, a careful history must be obtained of the symptoms; the possible bearing of the patient's occupation on the cause of the symptoms must be carefully considered. This is especially important in relation to toxic chemical poisoning—*e.g.*, alcohol, lead, and metallic poisoning, etc. The duration of the symptoms and their relation to food must be carefully gone into; also, the way in which the symptoms are affected by variation in the kind of food.

The tongue, teeth, gums, mouth, pharynx, and naso-pharynx must be examined.

The abdomen should be carefully examined, and the presence of any tenderness or resistance noticed; also, the presence of any abnormal lump in the region of the stomach should be looked for. Watch should be made for the presence of any peristalsis either of the stomach or bowel. Careful examination for any sign of enlargement of the liver, spleen or kidneys should be made, and any abnormal mobility of the kidneys should be noticed. Careful search must be made for any abnormal tumour in the abdomen.

By percussion and by combined auscultation and percussion, the outline of the stomach should be mapped out as closely as possible, and any dilatation or gastroptosis noted.

The state of nutrition, temperature, weight, and general appearance of the patient should be carefully noted. The heart and the circulatory system should be examined, and if the blood pressure appears abnormal, it should be measured by an appropriate instrument.

The blood should be examined if there is any special indication, such as anæmia or glandular or splenic enlargement. The respiratory system should be examined. The urine should be carefully examined for evidence of any renal disease, diabetes, gout, etc., and especially in cases where acid intoxication is suspected it should be tested for acetone and diacetic acid.

Examination should be made for the presence of any enlarged lymphatic glands. The nervous system should also be examined, and any abnormal signs noted. If headache is associated with the dyspepsia, then ophthalmoscopic examination for optic neuritis should be made. If pregnancy is the suspected cause, its signs must be looked for.

After a careful and thorough investigation of the case, usually an opinion can be formed as to the true cause of the dyspepsia, and then the appropriate line of treatment is indicated. I do not propose to consider in any detail the treatment of cases of dyspepsia other than those which arise from primary gastric causes. Thus, in the dyspepsia of bacterial infections, it is the toxæmia of the infection which requires treatment on the usual lines. In the dyspepsia due to auto-intoxications—*e.g.*, renal disease and gout—these conditions must be treated on the usual lines. In Addison's disease treatment is not likely to be of much avail. In

pancreatic diabetes it must be borne in mind that dyspeptic symptoms frequently are of grave omen, and precede the threatening coma of acid intoxication. The acid intoxication requires active treatment on the usual lines. In cases of dyspepsia due to recurrent vomiting or acid intoxication of various kinds, it is well to stop food by the mouth until the vomiting ceases, and to give large doses of alkalies by the mouth—*e.g.*, half-drachm doses of bicarbonate and citrate of soda in an ounce of water—every three hours; also a dose of calomel and saline purgative should be given. Normal saline containing 3 per cent. of glucose should be given by the bowel, 10 oz., every four hours. After the acute symptoms have subsided, careful dieting of the patient is necessary; thus, whey, lemon-water, citrated milk may be given, and later fruits, vegetables, and farinaceous food, with milk and butter, may be allowed. Meat, fish, eggs, soup and meat extract should be carefully avoided.

Treatment on the above lines of cases of acid intoxication is usually successful. These cases often present themselves as severe cases of acute dyspepsia, and unless care is taken they may be mistaken for functional dyspepsia. It is essential that the true cause should be grasped, for otherwise there is often grave danger from the acid intoxication present. The treatment of those cases due to chronic toxic chemical poisoning is, in the main, hygienic and prophylactic, the patient being placed under healthy conditions of life, and removed from any possible further poisoning. Cases of acute chemical poisoning require treatment on the usual lines, which it is not proposed to consider.

Cases of dyspepsia due to nervous causes require treatment of the nervous disease on the usual lines. Where there is any reflex irritation giving rise to the symptoms, this should be removed as far as possible. Cerebral conditions require treatment on appropriate lines.

The gastric crises of tabes or angio-neurotic œdema require treatment by local applications, such as warmth, sinapism, etc. Food by the mouth should be withheld.

Phenacetin may be given for two or three doses, or a dose of some powerful carminative mixture may be given—*e.g.* :—

Tinct. card. co., 1½ dr.
Tinct. zingib., ½ dr.
Tinct. capsici, 10 m.
Spt. ætheris, ½ dr.
Spt. chlorof., 15 m.
Aq. menth. pip. ad. 1 oz.

Every two hours.

If the pain continues morphia must be given hypodermically—*e.g.*, 1-5th grain, repeated if necessary.

Treatment of the tabes dorsalis or of the angio-neurotic œdema is very important in preventing the recurrence of these attacks of gastric crises.

Migraine is often associated with acid intoxication, and, if so, treatment on the lines above indicated—namely, purgation, administration of alkali, and a proteid-free diet—are indicated.

Dyspepsia due to diseases of the circulatory and respiratory system is best dealt with by treating the causal condition. The treatment of acute dilatation of the stomach, which sometimes occurs in these conditions, is referred to below.

The dyspepsia of blood diseases is best dealt with by the administration of remedies to benefit the causal condition.

In chlorosis, dyspepsia is an almost constant symptom. It must be remembered that chlorosis is usually associated with hyperchlorhydria; therefore, alkalies with the bland preparations of iron are indicated—*e.g.* :—

Sod. bicarb., 20 gr.
 Ferri amm. cit., 5 gr.
 Spt. chlorof., 10 m.
 Inf. aurantii, 1 oz.
 t.d.s.

To this may be added, liq. arsenicalis, 3 m.
 Nourishing, easily digestible diet—e.g., milk, fish, eggs, chicken, etc.—and aperient medicines may be taken. General hygienic conditions are most important.

In pernicious anæmia the gastric secretion is almost entirely free of hydrochloric acid and ferments. The best result in this condition will be obtained by giving after food, pepsine and hydrochloric acid—e.g. :—

Liq. arsenici hydrochl., 3 m.
 Glyc. pepsin, 1 dr.
 Acid hydrochlor. dil., 15 m.
 Tinct. card. co., 1 dr.
 Aq. chlorof., add 1 oz.
 t.d.s., p.c.

Or the tablet preparations containing pepsin and hydrochloric acid, such as lacto-peptine or acidol pepsin, may be prescribed. The food should be nourishing; milk, eggs, Benger's Food, meat juices, and peptonised food should be given. Preparations of hemoglobin should be given. Of course, the other methods of treatment—such as rest, the remedying of toxic conditions of the mouth, the increasing of the dose of arsenical preparation given, intestinal antiseptics, etc.—require great attention.

Cases of leukæmia, lymphadenoma, splenic anæmia require treatment on lines similar to those laid down.

THE TREATMENT OF DYSPEPSIA DUE TO DISEASES OF THE ALIMENTARY TRACT.

In every case any abnormal condition of the mouth should be remedied; carious teeth should be removed, pyorrhœa alveolaris should be treated. If there is some dysphagia, or if the symptoms of dyspepsia come on so quickly after food that œsophageal obstruction is suspected, then investigation should be made by passing a bougie, after carefully excluding the possibility of aneurysm. In cases of carcinoma of the œsophagus commencing near the junction of the œsophagus and stomach, the symptoms are those of chronic dyspepsia, the dysphagia often being only very slight. In cases of dyspepsia due to affections of the stomach, one has to consider the treatment of cases of acute dyspepsia of short duration, and cases of chronic dyspepsia.

ACUTE DYSPEPSIA.

This may be due to *dietetic indiscretions*. Here it is usually sufficient to withhold food by the mouth, and to give an aperient such as calomel, 2 gr., followed by a saline aperient. In severe cases an emetic of a dessertspoonful of powdered mustard in a tumblerful of warm water, or 30 gr. of carbonate of ammonia in half a tumbler of water may be given. Or the stomach may be emptied by the passage of a long soft stomach tube, and then washed out with warm water.

Acute Gastritis.—In this the pain may be relieved by hot applications to the epigastrium; the application of a mustard leaf, or mustard poultice, or the ice-bag. Food should be withheld for 24 hours. The stomach should be emptied either by the induction of vomiting after drinking warm water, or by the giving of a simple emetic, or by washing out with a soft tube. Calomel, 2 gr., with bicarbonate of soda, 5 gr., should be given after the stomach is emptied. Nausea may be relieved by giving a mixture of :—

Bism. carb., 15 gr.
 Sod. bicarb., 15 gr.
 Ac. hydrocyan. dil., 3 m.
 Spt. chlorof., 10 m.
 Aq. menth. pip., ad. 1 oz.
 4 tis horis.

In cases where the pain is very severe, it may be necessary to give a hypodermic injection of morphia 1-5th gr., or liq. morph. mur., 10 m., may be added to the bismuth mixture. Morphia should be avoided where possible. After the vomiting has subsided, liquids may be given—e.g., albumen water (made with the whites of three eggs added to one pint of normal saline containing 1 oz. of milk sugar), or whey, or citrated milk (1½ gr. of citrate of soda to the ounce of milk). The quantity of liquid given should be a tablespoonful an hour at first, and gradually increased. In the case of young children, calomel, ½ gr., with sod. bicarb., 4 gr., should be given, and repeated in six hours if necessary. Two drachms of the above bismuth mixture may be given. No milk should be given, but a little albumen water or normal saline, with 4 per cent. of milk sugar, may be given in doses of one tablespoonful an hour, and gradually increased.

If there is collapse, normal saline must be given subcutaneously or by the rectum.

Acute Dilatation of the Stomach.—In this condition the stomach should be at once emptied by means of the soft stomach tube, and the stomach washed out with warm water. The treatment should be repeated in three hours if necessary. Collapse must be treated by hypodermic injection of strychnine, 1-30 gr., or pituitary extract. Normal saline, 10 oz., may be slowly given by the bowel, and repeated every four hours. If necessary, the saline should be given subcutaneously. No food should be given by the mouth for 24 hours, and then the feeding should be as described under acute gastritis.

(To be concluded in our next.)

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by W. H. Willcox, M.D., F.R.C.P., Physician to Out-Patients, St. Mary's Hospital. Subject: "The Treatment of Dyspepsia."—(Concluded.)

ORIGINAL PAPERS.

ERYTHEMA NODOSUM AND TUBERCULOUS MENINGITIS.

By A. SEZARY, M.D.,

Medical Registrar to the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The close relationship of erythema nodosum to tuberculosis is now well known—in fact, although every such case of erythema nodosum is not necessarily of bacillary origin, every such case not shown to be due to some other cause is tuberculous *in posse*. This relationship was first pointed out by Dr. Landouzy on the strength of purely clinical observation akin to that which led him to assert the tuberculous nature of the so-called primary pleurisy, that is to say, erythema nodosum is sometimes met with in subjects recognised to be tuberculous, but more frequently in the subjects of latent or torpid lesions.

Attempts to provide anato-pathological data in support of this statement have not been very successful. Chauffard and Troisier claim to have determined erythema nodosum by intra-dermic injections of tuberculin, but in reality they deter-

mined a dermatosis, and not this particular dermatosis. Then, too, the reaction is not always positive. I myself have noted that it can be provoked in subjects who have never had erythema nodosum, and particularly in two cases of obese tuberculous subjects. The result seems to depend far more on the special cutaneous reaction of the subject than upon the particular agent employed.

It follows that, apart from the possibility of obtaining bacteriological confirmation, the doctrine of the bacillary origin of certain nodular erythematous repores almost exclusively on clinical data, which for that matter amply suffice to carry conviction.

The question therefore arises in respect of erythema nodosum just as in respect of pleurisy—viz., as to the future of patients thus affected. It is from this point of view that I should like to insist more particularly on a point of considerable interest—viz., the frequency of tuberculous meningitis in subjects, especially in children, who have had erythema nodosum.

My attention was attracted to this point by a case that came under my observation in February, 1910. The patient was a little girl, eight years of age, with well-marked erythema nodosum on the legs, accompanied by moderate rise of temperature that lasted three days. Examination of the lungs revealed unquestionable tracheo-bronchial adenopathy on the left side, with rough jerky breathing at the apex. Ultimately the little patient made a good recovery, and although still delicate, appeared to be in good health. Early in July I saw her again when she was manifestly unwell, was losing weight, had an evening temperature and had night sweats. The stethoscopic signs were the same as on the last occasion. She developed tuberculous meningitis to which she succumbed a month later.

Plenty of similar cases are on record in medical literature, though the sequence of events is not always the same. It is now currently admitted that erythema nodosum may be followed by, or culminate in, acute tuberculosis. Some authors, however, go still further, and state that it is sometimes the early symptom of an attack of tuberculous meningitis.

Erythema nodosum of bacillary origin, therefore, may complicate an attack of tuberculous meningitis actually in being, or it may antedate it some weeks or months. This is a fact of great clinical importance because it raises the question whether it may not be possible by appropriate measures to reinforce the resistance of the organism and so prevent the invasion of the meninges. It follows that a child who has had erythema nodosum must be regarded as a candidate for tuberculous meningitis, so that the eruption affords a valuable therapeutic indication.

We may well ask why it should be that tuberculous meningitis so frequently occurs in the course of an attack of erythema nodosum. Of this there are two possible explanations. To begin with we know that tuberculous meningitis is one of the commonest manifestations of the infection in the young, consequently it may be that erythema nodosum and meningitis are both consequences of a septicæmia which, apart from its cutaneous distribution, has a marked predilection for the meninges. The two structures may be attacked simultaneously or after an interval of several weeks or months. This hypothesis presupposes that the eruption is itself of a bacillary or toxic origin. Another explanation is afforded by rejuvenating the angioneurotic theory brought forward by Lewin, and suggesting that erythema nodosum may be the cutaneous manifestation of an imperfect meningial syndrome, possibly of bacillary origin.

We are all cognisant of the preponderant influence of the nervous system in the pathogenesis of dermatoses, some of which, Brocq's so-called cutaneous reactions, are manifestly of nervous origin. We know also that purpura, which often supervenes under very similar circumstances to those under which erythema nodosum occurs, and which, indeed, may be associated with the latter, is consequent upon a nervous lesion or some meningeal irritation which causes the eruption, and a hepatic lesion which determines the hæmorrhagic character.

Since the tuberculous nature of the eruption cannot be proved, either histologically or bacteriologically, the nervous hypothesis comes to the fore. Now the nervous lesion may be the meningitis *per se* or it may, as in tuberculous zona, consist simply in the meningeal reaction, as revealed by lumbar puncture. The latter, in spite of its innocuousness, may play a prominent part in the subsequent supervention of the meningitis by rendering the meninges more sensitive and more vulnerable to the tubercle bacillus. The latter, in the subjects of bacillosis, may be assumed to be specially amenable to the bacillus in presence of an outburst of bacillæmia. This hypothesis is analogous to, but not identical with, that put forward by Landouzy and others to explain the pathogenesis of bacillary arthritides.

In support of this hypothesis, we may recall the interesting case placed on record by Pons, who, having injected tuberculin in a patient suspected to be tuberculous, witnessed the supervention of grave nervous symptoms: violent headache, photophobia, diplopia, stiffness of the neck, hyperæsthesia, delirium and tachycardia. These symptoms, which pointed to the existence of meningitis, subsided a few days later, but two days after this improvement erythema nodosum made its appearance. In this instance the dermatosis was clearly consequent upon the nervous irritation.

If, therefore, we regard the influence of the nervous system as predominant in the pathogenesis of erythema nodosum (and this view concords very well with the general pathology of the dermatoses) the frequency of the supervention of tuberculous meningitis in this connection is easily explained by the hypothesis of nervous irritability just referred to.

However this may be with regard to the question of pathogenesis, it is our duty to bear in mind the fact that tuberculous meningitis is a common sequel of erythema nodosum, so that our prognosis should be extremely guarded.

EXTRA-UTERINE PREGNANCY, WITH SPECIAL REFERENCE TO ITS DIAGNOSIS AFTER RUPTURE OR ABORTION:

ILLUSTRATED BY SEVEN CONSECUTIVELY
OCCURRING CASES.

By J. NIGEL STARK, M.D., C.M., F.R.F.P.S.G.,
Surgeon, Royal Samaritan Hospital for Women, Glasgow; late
Assistant Physician, Glasgow Maternity and Women's Hospital.

So much having been written on extra-uterine pregnancy and the condition having been so thoroughly studied, it might reasonably be assumed that, at this date, its symptoms could, as a rule, be readily recognised and its diagnosis be as readily assured. Such an assumption would, however, be far from accurate. Although there are cases characteristic enough to be determined almost immediately by the least experienced practitioner, there are many others so puzzling and atypical that their nature can be settled only after an exhaustive examination and by a process of exclusion. Great skill may become acquired in diagnosing the diseases

of the female pelvic organs, but it is frankly admitted by even the most experienced gynæcologists that the road to accurate determination of the presence of extra-uterine pregnancy is so beset with pitfalls that they occasionally fall or go astray. For this very reason there is in this abnormal condition an element of interest wanting in others, such as uterine fibroids or ovarian cysts, which are so much more readily recognised. When to this uncertainty there is added the wonder and mystery of a pregnancy existing anywhere except in the maternal womb it can be no matter for wonder that almost every example of extra-uterine pregnancy is fraught with the deepest interest.

It must always be remembered that extra-uterine pregnancy is not to be dismissed as unworthy of serious consideration on account of extreme rarity, although even if it were very uncommon it might yet be the lot of any practitioner to be in a moment confronted with a case. It has indeed been asserted that there is an increase in its frequency, but probably this is more apparent than real, and the true explanation of this belief is that it is now more commonly recognised on account both of greater proficiency in diagnosis and more frequent abdominal section. Whatever the truth may be, it is indubitable that, since its first recognition by Albucasis in the eleventh century until now, thousands of examples have been seen, and more especially since Lawson Tait performed his first successful operation upon a ruptured pregnant tube twenty-nine years ago.

Two points in relation to extra-uterine pregnancy must therefore be borne in mind by every practitioner. The first is that there are many difficulties in diagnosing it, and the second, that it is by no means of uncommon occurrence. It follows, in consequence, that the conditions leading to error in judgment ought to be definitely known, that the absence of one or more of the "characteristic" signs and symptoms should not mislead, and that the possibility of its occurrence under the most unlikely circumstances should always be borne in mind. Perhaps a third counsel should be given—namely, to recognise it, if possible, either before or very soon after rupture or tubal abortion has occurred. This adds in many instances largely to the patient's chances of recovery.

The difficulties of diagnosis have lately been brought home to me by seven consecutive cases coming under my care within the last few months. Each of them furnished an illustration of some particular difficulty, and some were unusually puzzling. All possessed features of interest worthy of brief record.

1. This one was fairly typical in history and symptoms, but yet was not recognised at first, and the patient, after two attacks of pain, went about as usual, walking and riding in street cars, while in her pelvic cavity there was a tube distended with blood clot in the midst of which a fœtus was embedded.

Mrs. A., 36, had been married twice. By the first marriage she had five children, the youngest being nine years old. Labours and puerperia had been normal except the fourth, when there was puerperal septicæmia, after which there had always been some dull left-sided pain. From the second marriage, five years ago, there were no children and no miscarriages. Menstruation was normal in every respect, but had ceased three and a half months before I was consulted. Morning sickness was present. About ten weeks after the onset of amenorrhœa there was a severe and sudden attack of sharp, labour-like pains in the lower abdomen. It lasted about six hours, passing away gradually, and was followed for four days by bleeding like that of an ordinary menstruation. In a few days there was a second attack of cutting, irregularly recurring pains, after which a dull ache was felt in the left side. She was not confined to bed for more than a few days, and when her doctor arranged that she should consult me she called at my house. She was healthy-looking, complained of a moderately severe pain in her left side, and wished to know if she had actually had a miscarriage, and if so, if everything was away.

Examination showed the uterus in normal position, slightly enlarged, and an irregular, tender, doughy mass behind it and on its left. Operation was advised, and on opening the peritoneal cavity free

blood clot was found. The tube was removed, as there had evidently been a tubal abortion.

Pathological report: "There is great distension of the ampullary part of the tube, increasing outwards: the length is four inches and the greatest diameter is $1\frac{3}{8}$ inches. Fimbriæ are not seen, and the outer end of the tube is a rounded tumour from which blood clot can be peeled. When a thin slice is taken off the distended portion of the tube, parallel with its long axis, a gestation sac is opened, which has a small diverticulum extending towards the lumen of the tube. The placenta is in the slice removed: the fœtus is 18 mm. long, and is apparently seven to eight weeks old. Surrounding the sac is blood clot in which are chorionic villi."

When a woman whose menstruation is regular has a period of amenorrhœa for two or three months along with other signs of pregnancy, and is suddenly seized by severe cramp-like pelvic pains, and when, more especially, a doughy mass is felt on one side of the uterine body, tubal pregnancy should always be suspected.

2. Mrs. B., 29, 3-para, the last child 2½ years old. Forceps had been used at that time, and "inflammation of the womb" had followed. Since then there had been occasional pain in the left side. Menstruation had also been irregular, and before the present flow started it had been away for six weeks. At the end of that time there were retching, headache, abdominal pain, especially in the left side, and bleeding. For a fortnight rest in bed under medical supervision was taken. Defæcation increased the pain.

On examination I felt a mass over the left lower quadrant of the abdomen and filling up the left vaginal fornix, firm, dense, immovable, fixed to the uterus.

The history and the result of the examination decided my diagnosis of extra-uterine pregnancy. At the operation the large mass was found to be composed of intestine, adherent omentum, blood clot, and gestation sac. The clot extended into the pouch of Douglas behind, and to the left of the middle line in front. The left tube was removed, and the tissues forming the boundaries of the sac were brought together by catgut sutures.

Microscopically there were chorionic villi in the tubal clot. The tube had at one point a fusiform dilatation.

In this case there had been no suspicion of the presence of extra-uterine pregnancy. The amenorrhœa for three weeks after the period was due—although the irregularity tended to make this sign less trustworthy than usual—the pain, and the bleeding should all have roused suspicion which ought to have been developed into practical certainty by careful examination.

3. Mrs. C., 22, was delivered of her first child a little more than four months before I saw her. On the sixth day after the birth the temperature rose to 102°, on the next, with a rigor, to 106°. An attack of marked puerperal sepsis was passed through. She was sent to me in four months because she had never felt well since her confinement. She had had pain in her left side, a bearing-down feeling, and a more or less constant red discharge. There had not been any amenorrhœa nor any very acute attack of pain. Examination revealed a tender, firm mass to the left of the uterus, and it appeared fairly evident that this was an enlarged matted tube and ovary, the result of the puerperal sepsis. As the patient was a good deal worn out by the aching pain, and had never regained strength after the birth, it was deemed that the most satisfactory treatment was to remove the tube and ovary.

At the operation, blood clot was found in the peritoneal cavity. The left tube contained clot, and was removed. The right appendages were normal.

Later examination of the specimen showed that the ampullary part of the tube was greatly thickened, a mass of blood clot adhering to it, to the mesosalpinx, and to the ovary. In the midst of this clot was the mucous membrane of the tube. Decidual cells and chorionic villi were found in the distended portion of the tube and in the clot in its interior.

A more misleading case can scarcely be imagined. The post-puerperal sepsis so comparatively shortly before, and the probability that an inflammatory mass of matted tube, ovary, and exudate had been left as a result, seemed to point clearly to the existence of a subacute inflammatory condition. The patient had never been well, had been confined to bed off and on ever since, and it seemed almost impossible that pregnancy of any kind had occurred. There had never been any amenorrhœa. The more or less constant bleedings and the colicky pains were somewhat puzzling symptoms, and made the diagnosis uncertain. The case is another warning of the need always to bear in mind the possibility of extra-uterine pregnancy under even the most unlikely circumstances.

4. Mrs. D., 29, had been married four months before I saw her, and was a nullipara. Menstruation came a few days after marriage, then again, normally, a month later. Three weeks after this, two months before the patient was seen by me, sharp, cutting pains were felt for about two hours, and then bleeding began. A week afterwards there was burning pain in the abdomen. She was put to bed where she had been ever since. The pain gradually ceased, but bleeding had continued. Clots had occasionally been passed. She was tired and felt run-down.

Such was the history, in brief, and on examining, the cervix was felt short, softened, directed forwards; the uterus increased in size, slightly retroverted, its mobility impaired in all directions. The right fornix was occupied by a doughy mass of indefinite outline, and the left by a cystic swelling.

In the evening before operation, a sharp pain was felt in the left iliac region for about 20 minutes, and increased fullness was afterwards felt in the fornices. The temperature was 97.6° and the pulse 68, small in volume.

At operation, blood, free and clotted, was found in the peritoneal cavity. There were some adhesions of intestines in the pelvis. The left ovary was cystic, the size of a tangerine orange; part was removed. On the right side was a tubal pregnancy: the tube and part of the ovary were taken away.

Later, the right tube was found much distended in its outer aspect; the diameter 1½ in. The posterior wall of the tube, the mesosalpinx and the ovary were covered with clot. The distended tube contained blood clot, in which were chorionic villi. The cyst of the left ovary was about the size of a tennis ball, and there were two loculi.

Here, again, there were conditions liable to mislead. The nulliparity, the marriage so shortly before, the absence of amenorrhœa, morning sickness, or any other symptoms of pregnancy, all combined to lead astray the medical adviser.

But the continuous bleeding, the sudden attacks of sharp pain, and the doughy mass felt in the position of the tube should have aroused suspicion. Earlier operation would then have been performed, with consequent saving of pain and invalidism, as well as the avoidance of potential serious dangers, immediate or distant.

5. Mrs. E., 29, 1-para, the child being 16 months old. Menstruation usually lasted seven days, and was profuse, but otherwise normal. The last menstruation was eight days before I saw the patient, and had come at its proper time. There had been no amenorrhœa. Shortly before the period began there were intermittent pains in the left iliac region, with vomiting, dysuria and constipation. Later on the menstrual discharge was as usual, and was not prolonged. She was in bed for a fortnight before she was seen by me, and at the end of that time she had pretty acute abdominal pain and distension. The pulse was quick (120) and the temperature 99°. Purgation and high enemata greatly improved the condition, and the abdominal measurement decreased by an inch. Treatment on these lines was carried out for a week before operation.

The vaginal examination showed the uterus to be in normal position in front, but dextroposed. The left fornix was filled with a firm elastic swelling, extending upwards to the level of the anterior superior spinous process, and filling up the pouch of Douglas.

At the operation the peritoneum was found injected and the omentum adherent. The peritoneal cavity contained much blood clot. The left tube was greatly

dilated, and had ruptured. It was removed. On the right side the adnexa were freed and adhesions separated.

Pathological report: "The tube forms an elastic swelling, the greatest diameter of which is 3 inches by 1½ inches. On section the contents are solid clot in which are pale areas which, microscopically, show chorionic villi and decidua-like cells."

The chief difficulty in making a diagnosis here was due to the fact that menstruation had been normal and regular. This is not easy to explain in this particular case unless on the supposition that impregnation had occurred after the period before the last, and that what had seemed to be a normal period at the right time was really bleeding in connection with the rupture of the tube. The symptoms were much aggravated by severe constipation and intestinal distension by flatus.

6. Mrs. F., 39, 8-para., last child two years of age. Menstruation, always regular and normal, occurred as usual, and the last period was at the right date. Ten days after it ceased the patient was seized with sharp, cutting pains in the lower abdomen, on both sides, and in the region of the rectum. Some hours afterwards hæmorrhage began and was continuous until the operation, three weeks later. During this time there was much blood loss; weakness and giddiness were present on exertion; pain in the left iliac, sacral and lumbar regions was felt, intermittent and cramp-like and aggravated by stooping or walking.

The uterus was found in normal position; an irregular, tender swelling lay on its right side, though not quite in contact with it. The right adnexa were normal.

At the operation dark blood welled up. A very large clot, filling up the back and left part of the lower abdomen, was removed piecemeal, adhesions between tube and bowel being thus revealed. The gestation sac, with left tube and ovary, was removed.

Later examination of the specimen showed a fusiform swelling of the ampulla (2 inches by 1 inch); clot protruded at the ostium, and the tube contained clot in which chorionic villi were present.

This, again, as will be seen, was an atypical case, so far as the history was concerned.

7. Mrs. G., 40, 3-para, last child six years old. Menstruation was normal and regular. Six weeks, however, had passed without any appearance, and some sickness began to be felt. One evening, when the patient was walking out of doors, a sharp pain was felt, and almost immediately afterwards bleeding came on. After home was reached alarming collapse set in, and I saw the patient with her medical adviser after midnight. Although the pulse was rapid and weak, it was apparent to those around her that by this time rallying had taken place to some extent. Dulness was obtained in the flanks, and by the vagina fullness could be felt in the pouch of Douglas. As the patient lived in the country, it was decided to leave her in absolute rest, without even changing her clothes, and to remove her in an ambulance in the morning to a nursing home in town. This was done, and on operation a typically ruptured tube was removed, along with much blood, from the peritoneal cavity.

The chief features of this case were the suddenness of the onset of acute symptoms in such an unlooked-for fashion and the amount of blood lost, the patient being only a fortnight beyond her expected time for menstruation.

With the exception of this last case, not one of the series was diagnosed by the practitioner in attendance, and it must be confessed that in the second I was unprepared for the result of the abdominal section. The last was by far the most typical in every respect, and as it was one in which, not an abortion, but a rupture of the tube took place, the symptoms were extremely severe, the shock and pallor being specially well marked. There was, therefore, not much doubt as to the diagnosis.

Seven cases are too few to allow of any deductions being formed. They, however, at least, bring out this fact very clearly—that we cannot base a diagnosis of extra-uterine pregnancy upon any one sign or symptom or upon the history. Still, it may be instructive to analyse them in detail, however briefly, in search of

possible aids to the elucidation of our future cases.

1. As regards the age of the women, this varied between 23 and 40, so that we cannot depend much upon this point. But it is noteworthy that three were 29 years of age, and it has been noted by others that extra-uterine pregnancy is specially liable to occur in a woman of 28 or 29. In that respect, therefore, these seven cases are characteristic in showing the extremes between which the condition may happen and the special predilection for the year or two below 30.

2. Previous pregnancies.—Only one woman had borne a large family—eight children. One had not been pregnant before, and two had had only one child. We can lay no stress in diagnosing the condition upon the number of previous pregnancies, and we must recognise that even during the first few months of married life there may be an abnormal pregnancy.

3. Cessation of menstruation.—In no fewer than four of the women there had been no amenorrhœa, and we must therefore always remember that we are not justified in declaring that because menstruation has been perfectly regular there cannot possibly be extra-uterine pregnancy.

4. Pain was a feature common to all of the seven cases, and it is practically always a prominent and characteristic symptom of ectopic pregnancies after rupture or abortion. The pain is situated in the lower part of the abdomen; usually it is unilateral, often recurrent, generally very severe, and as a rule it is sudden in onset. Each of these qualities of the pain should be carefully held in our remembrance, because, taken together, they provide the most trustworthy symptomatic evidences of the existence of extra-uterine pregnancy at the stage when first seen by the practitioner.

5. As a rule, in addition to the pain there is a second significant guide to correct diagnosis—hæmorrhage from the uterus. This occurred in six out of our seven cases simultaneously with, or shortly after, the initial pain. The amount was never very serious, but the most arresting feature of the bleeding, one which should always arouse our suspicions, was that the accompanying faintness and pallor were out of all proportion to the quantity of blood lost per vaginam. In these cases this is due, of course, to the concealed intra-tubal or intra-peritoneal hæmorrhage going on at the same time.

6. The physical signs were in our cases those usually found. In the last, which was very acute and due to total rupture, and which I saw within a few hours of its occurrence, the abdomen was somewhat distended and there was dulness over the flanks, but very little could be made out per vaginam. In the remaining six the uterus felt enlarged, and a mass, ill-defined and doughy, occupied the site of a tube, and in three of these the pouch of Douglas was also the site of a swelling.

Undoubtedly there are very puzzling cases of ectopic pregnancy, and no better example of one could be given than the second in our series. For our encouragement it can be confidently asserted that no man, however experienced, could have made a positive diagnosis. Fortunately, however, the course of treatment was very evident and plain, whether the case was one of extra-uterine pregnancy or of an inflammatory or suppurative condition of the tube and ovary, and it effected a cure—as it always would do under similar circumstances.

An ordinary uterine miscarriage should usually be easily distinguished from a tubal rupture or abortion. The pain in the former ceases after expulsion of the ovum, and is felt in the back or hypogastrium; while in the latter it is generally unilateral, in front, recurrent, and much more severe. There is only the enlarged uterus to be felt in the former; but in the latter there is, in addition, a swelling at one side. These are the chief points of differentiation.

It is at all times our duty to diagnose the presence of extra-uterine pregnancy at as early a date as possible, and that for several reasons. (1) Because women have bled to death in acute rupture with huge intra-peritoneal hæmorrhage, and the good general surgical principle, that bleeding ought always to be arrested as quickly as possible, should be followed. This class of

case is, however, usually so characteristic and dramatic as to present few difficulties in diagnosis, and nowadays is, as a rule, treated early. (2) Because we ought not to leave the future to chance when we are dealing with cases less severe though similar in nature with those last mentioned, since we never can tell at what moment a serious secondary bleeding may occur. (3) Because in milder cases of tubal abortion with hæmatoceles adhesions may follow later and cause pain, the sac may enlarge from further bleedings, suppuration in the clot may occur and result in sepsis.

It is impossible for anyone to foretell what may happen, and, therefore, whether for the sake of safety to life or for the prevention of weeks, or even months, of invalidism, an early diagnosis, followed by early treatment, is most emphatically necessary in all cases similar to those recorded in this paper.

THE INGLEBY LECTURE

ON

PUERPERAL FEVER. (a)

By J. FURNEAUX JORDAN, B.Ch., F.R.C.S.,
Surgeon to the Birmingham Hospital for Women, and the
Maternity Hospital.

(Concluded from page 13.)

(4) Mrs. C., æt. 26. First confinement. Patient generally septic. Confined on April 16th, 1911, attended by a midwife, who, as the labour proved difficult, called in Dr. Norton, and with great difficulty she was delivered with forceps. She remained for six days quite well, but on the seventh day she felt ill, hot and feverish, and on the eighth day she had a rigor and remained in a condition of fever, with several rigors occurring, until admitted on April 28th, that is the thirteenth day after confinement. On admission temperature was 103, abdomen tender, uterus tender, with some thickening around it. Patient was nursed, bowels were kept open, and her temperature coming down gradually the first few days I hoped that the induration around the uterus and the cellulitis would absorb of itself, but in the next six days her temperature went gradually up again to 103.5. I operated on May 9th, making an incision into the cellulitic deposit per vaginam, opening two small collections of pus and draining them. The uterus was explored, and swabs taken for culture and possibly vaccine preparation. For the next 6½ weeks her temperature was up every evening and down every morning, up to anything between 99.5 and 102, and down in the morning to normal, sometimes sub-normal. The cultures showed pure streptococcus. She had vaccines every fourth day, but they seemed to have no effect upon the fever. The patient's general condition improved a little at first, and then remained stationary; all this time she expressed herself as feeling well and free from pain though so weak that she could not sit up in bed. In the seventh week the rise of temperature at night becoming higher, I made more frequent examinations, and on the forty-sixth day I opened another small abscess behind the uterus. The temperature fell after this, but there was still some evening rise, but gradually she became nearer and nearer to normal, and in another three weeks she was put to sleep out of doors in the garden. For seven more weeks she lay there looking better, feeling better, her temperature up to 99 sometimes at night but normal in the morning, but so weak still that it was impossible for her to get up, and in spite of her feeling and looking better there was no gain in weight, she having become, and remaining, extremely emaciated. About the middle of August her temperature rose again three or four times in a week to over 101, and as I was away on my holiday, Mr. Hewetson saw her for me, and found some induration in the right groin. He opened this, letting out some pus, on August 24th. Her temperature at once became normal, and remained so for the five more weeks that she remained in hospital. Her recovery after this was steady, but extremely slow, and even when she left the hospital she was a thin, pale, anxious-looking woman. I saw

(a) Delivered at the Birmingham University on May 23rd, 1912.

her a month ago looking and feeling very well. Duration of stay in hospital five months.

(5) Mrs. L., et. 32. Six children. Prematurely confined on February 16th, 1911, attended by a neighbour. On the third day was taken ill with shivers, and getting worse, Dr. Petrie was sent for on February 22nd, and I saw her with him on the 23rd. Patient was wandering, and in a state of acute sepsis; temperature 103.6; sordes on the lips; dry furred tongue; abdomen tender, but not distended; pulse over 140. At the time I did not expect her to live 24 hours, and hesitated about moving her to the hospital for fear that she should die on the way. She had two more rigors in the first 24 hours after admission, and an injection of anti-streptococcic serum was given, while intra-uterine swabs were taken for the purpose of examination, and preparation of vaccine. On the third day after admission she had six minims of her own vaccine (30 million), and subsequently she had an injection of vaccine every third or fourth day for the next fortnight; but as the rigors persisted and her temperature rose most days to 104 or 105 and sometimes to 106, the vaccine treatment was stopped. The cultures made from swabs showed pure streptococci. In the third week she had a rigor every day, her temperature on two occasions going off the chart up to 108.4. On two other occasions it was up to 106 and 108 respectively. After the vaccine treatment was suspended, blood cultures were made, and proved to be sterile. The patient was never completely conscious, and her death was expected every day, but in the fourth week she improved a very little, she only had three rigors, and for 2½ days her temperature was normal. The fifth week had two rigors, but her temperature on the whole higher, rising on four occasions above 102, and the patient became more and more prostrate. At the end of the sixth week she began to cough and her breathing was more laboured. An examination of the chest revealed no definite pneumonia, no definite area of dulness, moist breath sounds. The condition of the lungs did not get any worse, but the patient gradually got weaker and weaker, and died on April 7th.

Post-mortem.—Body well developed; very anæmic. Abdomen: No peritonitis, though there are some shaggy tags on the cæcum and lower end of ileum, as if there had long ago been some local peritonitis; uterus, etc., free and apparently normal; no pelvic cellulitis nor phlebitis. In the interior of the uterus a small projection like the top of a small mushroom from the centre of the fundus covered with a yellow purulent exudate; liver large, normal colour, no abscesses; kidneys large, pale, subacute parenchymatous nephritis; spleen enlarged. Thorax: No pleural effusion and no adhesions, some yellow lymph on both lungs, lungs infiltrated throughout with nodules as large as small marbles; most of these on section are abscesses and full of dirty pus, some of them are reddish and solid, evidently a septic broncho-pneumonia showing infected area in various stages. The lung between the nodules is singularly unaffected and practically normal; there is no pus in the bronchi, and none of the abscesses appear to actually communicate with a bronchus. Pericardium contains 4 ounces of serum; heart is flabby, no valvular disease.

Microscope.—The mass at the top of the uterus is placenta undergoing organisation, shows no evidence of acute inflammation and contains no micro-organisms. The pus from the lung abscesses is crowded with germs of all sorts, and of types usually found in the air passages, so that although the primary lung infection was probably a metastasis, the majority of the abscesses owe their origin to a dissemination by the smaller tubes, and the contact of the air has allowed the infection to become mixed. There are streptococci and Gram-positive diplococci, Gram-negative diplococci like *M. catarrhalis*, and short and long Gram-positive diphtheroid germs of all sorts.

From a consideration of these and somewhat similar cases we learn that even when the temperature has come down to normal, the tongue has cleaned, and all abdominal pain and tenderness have disappeared, unless also the patient gains steadily in strength, puts

on weight, and is able to get up, the most careful and continuous care must be taken that any surgical condition—as, for example, an abscess—will not be overlooked, for in these cases the abscess will form a swelling free from pain, free from tenderness, and free from redness. We learn that on the slightest complaint of any trouble with respiration or pain in the chest, or with any cough, a careful examination of the chest must be made. We learn that the abscess tends to form in a dependent part of the body, and I think I may add that we learn also that when these surgical conditions supervene during the time that the patient is under vaccine treatment, they are never acute, and if open to surgical treatment are easily cured.

CAUSATION.

It is usually the custom to deal with the ætiology of a disease at an early stage of a lecture or paper. My excuse for leaving it till now is that I always share in the feelings of a little boy who has a jam tart and who eats all the circular rim of dry paste first and leaves the jammy centre for the last mouthful. I do not mean to imply that I am going to give you anything very different from the circular rim, but merely something that is, I think, a little less dry.

When we think of the usual surroundings of the new-born babe we ought to be surprised not that there is so much puerperal fever, but that there is not a good deal more. In direct contact with the patient, in direct contact with the doctor's or midwife's hands, in direct contact with any tear or wound that may be inflicted are, in most of the working-class houses, blankets, or sheets, or clothes that even if not describable as dirty, cannot by any stretch of the imagination be called surgically clean. It is surely legitimate to ask why sterilised towels should be placed all round the field of an operation and not around the field of a delivery; the latter being even more exposed to the risk of infection than the former. We take infinite pains to keep from an operation wound staphylococcus, bacillus coli, streptococcus pyogenes, etc. Do we, can we honestly say that we do invariably take the same pains to keep them from a cervical or perineal tear in a confinement? The doctor in attendance will invariably tell you that he thoroughly sterilised his hands, that his forceps were boiled, also any sutures and needles that he used; but is there as much attention paid to cleansing the patient as there is to cleansing the doctor's hands? I think it may truly be said that there is not, and, as I shall show you in a few minutes, it is here that the danger lies. Before a difficult forceps case is finished the hands of the attendant must frequently come into contact with the thighs, vulva, and abdomen of the patient, and although they may be thoroughly sterilised to start with, it is incredible that they remain so to the very end. If we hold the view that puerperal fever is only taken to a case from a previous one, that the causative germ comes into the room on the attendant's hands or instruments, and is not present on or in the patient, then the ordinary method of procedure would be sufficient; but let us examine this causative germ for a few minutes. I give here the results of the bacteriological examination of the uterine discharge as shown in cultures or cultures and films in 21 cases of puerperal fever—nearly all of which have been under my own care.

- (1) Pure bacillus coli in cultures and films.
- (2) Cultures showed pure streptococcus and a few colonies of staphylococcus aureus, sputum crowded with streptococci.
- (3) Streptococcus and diphtheroid bacillus.
- (4, 5 and 6) Pure growth of streptococcus in cultures.
- (7) Cultures showed streptococcus and bacillus coli mixed.
- (8) Profuse and pure culture of staphylococcus albus.
- (9) Cultures showed staphylococcus aureus. Some doubt as to this causing puerperal rise of temperature; three days later pus evacuated from Douglas's pouch, cultures from the pus showed streptococcus and bacillus coli. (This was a case of Mr. Martin's.)
- (10) Cultures showed streptococcus and diphtheroid bacillus, bacillus coli and staphylococcus albus. The

swabs were probably contaminated from the vagina. (This was a case of Dr. Edge's that died on the fourth day of peritonitis.)

(12) Pure growth of streptococcus in cultures.

(13) Pure growth of streptococcus in cultures, also from the pus of a secondary abscess.

(14) Cultures showed profuse bacillus coli and few streptococci.

(15) Pure growth of streptococcus in cultures.

(16) Pure growth of streptococcus in cultures, also from the fluid taken from the pleura.

(17) A fine colony of streptococci, but not same as the streptococci in the other puerperal cases.

(18) Few bacillus coli, but chiefly a Gram-negative bacillus in tiny colonies.

(19, 20 and 21) Pure growth of streptococcus in cultures.

Dr. Mackey, who has done all the bacteriological investigations, tells me that the streptococcus which is present in 17 of the 21 cases is quite distinct from other streptococci, is the same identically in all these 17 and that in any secondary pus, pleuritic fluid or sputum, it was identical with that found in the uterine discharge. He also tells me that he has never found it in any other septic cases, and only once has he seen it apart from these puerperal cases, and that was in the cerebro-spinal fluid of a chorea gravidarum.

We suggest that it might be called the streptococcus puerperalis.

Its characters are as follows:—It grows freely upon agar, producing opaque colonies which are much larger than any other streptococci, so much so that after 48 hours the colonies might easily be mistaken for those of staphylococcus albus; in both it produces chains of moderate length which have little tendency to form clumps or entanglements. Its fermentation tests are as follows:—It produces acid and clot in milk, acid in lactose, in glucose, saccharose and salicin, no change in raffinose, mannite and inulin. These reactions show that it differs from the streptococcus faecalis in its action to mannite, and from the streptococcus pyogenes by its production of clot in milk. Since this definite streptococcus has been found on bacteriological examination in the uterine discharge in 17 out of 21 cases—that is, in 80 per cent. of the cases—we have a *prima facie* right in assuming that this is the most frequent cause of puerperal fever. It must not, at the same time, be forgotten that cases have been shown to be due to infection by bacillus coli, staphylococcus aureus, and other kinds of streptococci. Since this streptococcus puerperalis is found nowhere practically but in these puerperal cases, it would be foolish to think that doctors or midwives convey the infection to the patient, it would be still more foolish to think that the infection cannot be conveyed from one patient to another. This sounds paradoxical, but it is well known to you that puerperal fever does and will occur in isolated cases. A doctor will for a long time be free from a case, then he gets one, and possibly after another very long interval he will get another. If one follow the other closely, if while attending the first the second were infected, it is possible that he might have conveyed the infection from one to the other, but in isolated cases where does the infection come from? A simple explanation, and one that requires, and will get, for its proof or otherwise, further investigation, is that this streptococcus, like the streptococcus faecalis, is present in the contents of the bowel, and that the puerperal woman is very susceptible to its action. Efforts will be made to discover and isolate this germ from the faeces. Its presence in the bowel will explain everything, including those cases in which, in spite of many precautions, fever occurs.

You will remember that in three of the cases reported it was associated with bacillus coli, and it is not difficult, therefore, to understand how easily the puerperal uterus becomes infected from the rectum. Even the separating bridge of the perineum may be absent at the end of a confinement, so that the passage of the streptococcus from the rectum to the uterus is actually facilitated. That perineal and rectal operations are not followed by infection by this streptococcus we may look upon as due to the fact that all such operation

wounds, when there is a possibility of discharge-collecting, are drained.

Now it is obvious to everyone that after the confinement is over the cavity of the uterus, if there is the slightest fault in involution, will remain as an inert bag containing more or less blood clot and serum. Here we have a ready soil in which these streptococci can multiply, a soil, too, that is in direct contact with a surface immediately ready for absorption. This explanation, then, although not fully proved, explains both the occasional sporadic nature of the case and also the facility with which one puerperal case will infect another.

TREATMENT.

(1) *Preventive*.—There can be little doubt in the minds of any of you as to the lines that should be followed in order to keep your patients free from puerperal fever.

It may be recalled that the streptococcus puerperalis was associated three times with the bacillus coli, the bacillus coli was found alone in one case, a profuse growth of bacillus coli with a few streptococci occurred in another, the staphylococcus aureus in yet another, and lastly a fine colony of streptococci unlike the streptococcus puerperalis in another. Bearing these facts in mind, and also the theory that the streptococcus puerperalis is present in the bowel, it will be recognised by all that absolute surgical cleanliness not only of hands and of instruments is essential, but equally essential is the absolute surgical cleanliness of the patient's skin. The whole area of the field of delivery should be thoroughly cleaned—The thighs, the vulva, and the abdomen; the hair should be clipped quite short, and if any obstetric operation has to be performed I think it would be better to shave it off.

Since at the beginning of labour an enema is given to ensure as far as possible that the rectum shall be empty during the delivery of the baby, it follows that the neighbourhood of the anus has recently been infected by contact with the contents of the bowel. It is our especial duty to pay greater attention than we have done to cleansing the region of the anus. However well the rectum is emptied it usually happens that more or less of the bowel contents are expelled in the last part of the second stage of labour. It is wise to have a bowl of solution of biniodide of mercury (1 in 1,000) close at hand with some biggish pieces of absorbent wool in it, and as any faecal matter escapes wipe it away thoroughly from front to back with the solution; thus will any possible infection be carried away from the vaginal opening. Care should be taken not to soil one's fingers in doing so—to be successful in this the pieces of wool should be of large size. Always wear a sterilised gown, and take three or four sterilised towels to place under the patient and over the edges of the turned-up patient's clothes and turned-down bedclothes. If there is a nurse in charge beforehand, she can prepare the sterilised towels before the stage of labour at which they will be required is reached. We must cleanse our hands before we start cleansing the patient, and after cleansing the patient we must clean our own hands again, and then put on the gown and place our towels ready in position. Some of you will at this stage put on rubber gloves that have been boiled, others will not. If a man has absolute faith in the power he has of sterilising his hands he may or may not wear gloves; if he has not this faith, then the wearing of gloves or not will make no difference; for in midwifery work, above all other, it frequently happens that a hole may be torn in the glove and unless the hand inside it is absolutely sterile the glove will have been useless.

To my mind, the great advantage of rubber gloves in surgical work is that you can by their means protect your hands from sources of infection. The method that will be used for cleansing the skin of the patient you must decide for yourselves. Personally, I am a great believer in thorough scrubbing with a sterilised loofah with soap and hot water followed by vigorous rubbing with a dry sterilised towel, then a thorough rubbing with methylated spirits, to be followed finally

by rubbing with a solution of biniodide of mercury (1 in 500) in 75 per cent. of methylated spirits.

I think I am right in saying that Mr. Leedham Green's experiments on sterilising of the hands have shown that this method gives the best results.

After what I have told you, is there anything else that we can think of that will help in the prevention of puerperal fever?

I do not think it is a dream impossible of fulfilment that every woman at the commencement of labour shall have an injection of the vaccine of a streptococcus puerperalis, thus rendering her immune beforehand to the infection by this germ. This, at any rate, would render her immune in 70 or 80 per cent. of the cases.

Further consideration even might lead an enthusiast to inject also a vaccine prepared from the bacillus coli.

It may be said that this elaborate method of cleansing—sterilised gowns and towels, rubber gloves, and even more, stock vaccines, will involve such an expense that the extremely moderate fee that is received by the practitioner for attending a woman at the most critical period of her life is insufficient to justify one in incurring it. Surely the occurrence of one case of puerperal fever will involve such an expenditure of brain power and of time that this very moderate expenditure in every case is to my mind not only justified but essential. I speak now of the expenditure on the methods of sterilisation and not of the expenditure on stock vaccines. As I have already hinted, this preliminary injection of stock vaccines may be only a dream of mine which may, or may not, be fulfilled.

Before we leave the question of preventive treatment I may add, although it is hardly necessary to do so, the importance of impressing upon the patient beforehand the importance of a clean, well-aired room, of clean blankets and clean sheets. If possible, too, the patient should have a good warm bath before labour begins or as it begins.

(2) *Treatment of the fever when the temperature rises.*—When the first rise of temperature is in the first 48 hours and is only a slight one, up to or just over 100, when there is no great rise in the pulse-rate and the patient does not feel very ill, the best thing to do is to wash out the uterus with an antiseptic solution, seeing to it carefully that all the apparatus used is scrupulously clean. In many cases the temperature will fall the next morning and never rise again. If the rise in temperature over 100 persists over two days, or occurs a second time, we must conclude that there is fever more or less severe.

It would be a very good thing if every case of puerperal fever were immediately notified to the Medical Officer of Health, and then institutional treatment will be available for those who cannot possibly afford suitable treatment at home. The majority of these latter will probably be the midwives cases to which, when the temperature rises, the doctor has been called in. Those who can afford suitable treatment can be immediately treated at home, but immediate notification means immediate treatment for those who cannot so afford it. The number of cases at present notified to the M.O.H. in this city is only a small proportion of the cases that occur. You would hardly believe it when I say that the number notified to the M.O.H. is actually less than the number admitted to the ward at Sparkhill.

For any treatment to have a chance of success it must be started early in the disease. What I would advise is this:—That the patient be placed on her left side with the knees drawn up, that the doctor, wearing sterilised rubber gloves to protect his own hands from infection, should pass a duck-bill speculum and swab out the vagina with a mild antiseptic solution by bits of wool held in a vulsellum forceps. Having done this, he should catch hold of the anterior lip of the cervix with the vulsellum forceps and pull the uterus a little downwards and forwards so as to expose the external os; a second person will, of course, hold the speculum, and then the doctor holding the forceps in the right hand will take a sterilised swab such as shown here, and taking care that it does not touch any of the parts on the way, will push it

through the os into the interior of the uterus, will draw it out with equal care, and immediately cork it tightly in a sterilised test-tube. By bacteriological examination of this swab he has a certain means of ascertaining the nature of the infection. He should then by manual examination try to satisfy himself that the interior of the uterus is clear of any retained placenta or membranes. If there is any doubt of this, holding the cervix as before in the vulsellum forceps, he can pass a blunt curette into the uterus and run it over the whole of the inner surface of the uterus, then swab out the interior with a piece of wool, either on a wooden probe or held on long forceps and dipped in the dilute solution of biniodide of mercury, and finally insert into the uterus a strip of iodoform gauze to act as a drain. Following on this I think it would be advisable to give the patient an injection of vaccine containing 25 or 30 million of the streptococcus puerperalis.

I may say here that I do not doubt that very shortly stock vaccines will be prepared from this streptococcus, and will be placed on the market.

Believing as I do in the efficacy of a vaccine prepared from the source of the patient's infection—what I may call the patient's own vaccine—I would advise that, whenever the patient can afford it, you have one prepared, and as soon as possible give her an injection of it.

The question of expense must enter into this treatment. The preparation of vaccine involves several hours' work, and can only be done with absolute safety either by or under the immediate supervision of a skilled bacteriologist. You will be the first to admit that such services must be paid for.

I think I may claim from some of the results in the treatment by this method that I have given you that I am justified in asking you to adopt this treatment. I quoted three severe cases where this treatment was applied early with complete success, and even in those prolonged, drawn-out cases in which the vaccine did not appear to have an immediate curative effect, I would point out that, when what I called a surgical condition—such as the formation of an abscess—appeared, it was only accompanied by a slight irregular temperature, by no fresh general septic condition of the patient, and after the abscess was opened the recovery was immediate and complete; whereas, in cases which did not have the vaccine treatment, any fresh surgical condition was accompanied by an increase in the general septic condition of the patient, leading ultimately to a fatal end.

I do not claim for one minute that if the patient has been profoundly infected by the toxins of these streptococci, and if the infection has been prolonged for some time, it is possible to bring about immunity and recovery by the injection of vaccines; but what I do ask that we should all aim at is, that the patient should be given a chance of becoming immune to the infection before her powers of resistance have been too far overcome by the degree and the duration of the infection.

I would like to add here one or two other examples of treatment by this method. Let me give you a case that has come under my care after most of this lecture was written:—

Mrs. J., æt. 25; confined April 8th; normal confinement; primipara.

Had a rigor April 9th; temperature 104.2. Admitted to the hospital on April 11th. On admission in the night I was rung up by the matron, who told me that the patient was so ill that she did not think she would live till the morning. I ordered stock vaccine, 30 million of the streptococcus puerperalis. When I saw her the next morning her temperature had begun to go down; she was delirious, trying to get out of bed, picking at the bedclothes, dry and almost black tongue, sordes on her lips, pulse that I could hardly count and very feeble, uterus big and tender, abdomen slightly distended and tender, no tear in the perineum. I took swabs of the interior of the uterus. Dr. Mackey reported an infection of a streptococcus puerperalis and bacillus coli. During that day her temperature fell to 101, but went up again the next

day to 104.8, and she had two rigors. Her temperature remained up until the third day after admission, when she had a dose of her own vaccine—4 minims, containing 20 million streptococci and 100 million bacillus coli. Her temperature came down rapidly to normal, and has never risen again, although it was some days before she became quite clear in her mind, and before her tongue became clean and moist; she had a second dose of her own vaccine four days later of 25 million streptococci and 120 million bacillus coli. Her temperature remained normal, but on May 5th I noticed a small swelling at the back of the right buttock. The next day I found that this was larger and fluctuating, and under a local anæsthetic I opened it and let out about 10z. of pus, there being no rise of temperature; and by this time the patient, who had had altogether four doses of her own vaccine, was expressing herself as feeling very well and anxious to get up. Under ordinary circumstances I would certainly have said, when I first saw her, that this patient had not a chance of recovery.

Showing the advantage of treatment by the patient's own vaccine as compared with stock vaccine, there is the case of

Mrs. T., æt. 36; confined by a midwife; fairly profuse post-partum hæmorrhage; on second, third, and fourth days had rigors; on the fifth she was seen by Dr. Barber and by myself; temperature 103.6; in acute septic condition. Admitted to the hospital the next day, and the usual treatment was followed out. Dr. Mackey's report showed that infection was due to bacillus coli, but chiefly to a Gram-negative bacillus in tiny colonies smaller than the streptococcal colonies, which I think I am right in saying that Dr. Mackey said he had never seen before. Her temperature was irregular for the first nine days after admission, but usually varying from 101 to 103. After the second dose of her own vaccine on the ninth day, containing 60 million bacillus coli and 15 million of the other bacillus, her temperature came down steadily, and, although it subsequently rose twice to 101, her recovery was continuous and complete.

A second case, also showing the advantage of her own vaccine, was that of Mrs. P., who was admitted on the fourteenth day after her confinement with all the symptoms of puerperal fever. Cultures showed streptococcus and a few colonies of staphylococcus aureus. On admission she had a bad cough, there were crepitations behind the left apex, and the sputum was crowded with the same streptococci. She had one dose of her own vaccine, containing 20 million streptococci and 200 million staphylococci; her temperature came down to normal and never rose again.

In addition to this treatment by vaccines, none of the ordinary methods of treatment should, if indicated, be neglected:—Intra-uterine douching with dilute antiseptics, iodoform pencils in the vagina if the discharge is offensive, tonics, careful attention to the bowels, and, when necessary, stimulants.

I have now come to the end of my lecture. I chose the subject, as I told you, because I thought it was one of interest to the majority of medical men. I may say now that I chose it also because I was anxious to impress upon you the possible advantage that your patients may derive from your knowledge of this vaccine treatment. I may have formed my conclusions too hastily, and you may say that they are not warranted by the number of cases investigated. I can only say now that I am going on with these investigations, and further results will be published when they are ready. I chose this subject, too, because it has always seemed to me that the death of a woman in childbirth from puerperal fever is a matter of reproach to the medical profession, and any possible advantage in treatment that may be derived from investigations into all aspects of the disease should be—and will be, I am sure—heartily welcomed by the profession.

No one is more conscious than I am of the inadequacies of my lecture, and any little merit that there may be in it I owe almost entirely to our bacteriologist, Dr. Mackey. To him I give my deepest thanks. I have also to thank—and I do it with

pleasure—my colleagues on the staffs of the Women's and Maternity Hospitals; and, finally, gentlemen, I thank you for your attendance here this afternoon.

OPERATING THEATRES.

HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL.

CARCINOMA OF THE CERVIX UTERI.—MR. JACKSON CLARKE operated on a woman, æt. 60, who had been admitted for recurrent metrorrhagia during the previous twelve months. The general condition of the patient was satisfactory. On vaginal examination, the external os was found to be irregular and nodular, and the entire cervix was hard and slightly enlarged. The fornices were carefully palpated, but no evidence of extension of the disease into them was found. There had been no symptoms pointing to implication of either the bladder or the rectum, nor was any evidence of such extension detected during the examination.

At the operation, the vagina having been well douched out with dilute lysol solution, the interior of the cervix was curetted, and the fragments thus brought away being obviously carcinomatous, the abdomen was opened by a median incision below the umbilicus and its cavity carefully palpated for possible secondary growths. No such having been found, the patient was put in the Trendelenburg position, and complete hysterectomy (after Wertheim's method) was carried out, the chief steps being: First, incision of the right broad ligament, ligation of the corresponding ovarian vessels and round ligament; secondly, the uterine vessels and the ureter were then exposed and the uterine artery ligatured external to the ureter, which was next freed from the surrounding uterine and vesical veins up to its attachment to the base of the bladder; thirdly, the peritoneum was incised across the front of the body of the uterus, and the bladder was carefully pushed down clear of the uterus and of the uppermost part of the vagina. The left broad ligament was now incised, and the parts in and below it were treated exactly as had been done on the right side. Careful search was next made for enlarged glands along the internal iliac vessels, but no such glands were found. It proved difficult to free the terminal part of the left ureter, the cancerous tissue coming rather close to it in this situation, and making it the more important to dissect away the blood-vessels as close to the pelvic wall as was safe. This having been done, the utero-sacral ligaments and the peritoneum across the bottom of Douglas's pouch were divided. The parts were now ready for removal, but at this stage a little more delay was caused from the fact that owing to the shortness of the vagina it was found impossible to apply the clamps as is usually done. The vagina, therefore, was mapped out with 1 in 20 carbolic solution and then divided by scissors from within the abdomen. The cut edges of the vagina were then united by catgut stitches threaded on curved needles and passed so as to miss the mucous surface. The cut edges of the peritoneum were next united by continuous catgut suture. The patient was then lowered into the ordinary dorsal position and the anterior incision closed in three layers.

Mr. Clarke said that during the past two years some six or seven patients had been admitted to the hospital on suspicion of their having cancer of the uterus. All except the case under consideration had proved to be something else, some less formidable affection being discovered. As to operative details, a good view of the pelvis was obtained by using a Doyen's retractor at the lower part of the wound, and a self-retaining double retractor at the upper part.

The operation was somewhat prolonged by the two circumstances before referred to, and the patient suffered from shock to a moderate extent, but she rallied well under the ordinary care and made an uninterrupted recovery. Three weeks after the operation she was convalescent.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JULY 3RD, 1912.

DR. JAMES RITCHIE in the Chair.

DR. W. T. RITCHIE, for Dr. LOVELL GULLAND, showed a man, *æt.* 26, suffering from
LYMPHADENOMA.

There was enormous glandular enlargement. One of the glands had been excised and showed the typical changes of the condition. The leucocytes numbered 32,200 per c.mm., with 86 per cent. of polymorphs. There was no excess of eosinophils, but evidence existed of large intra-thoracic growth. There had been some improvement after an injection of salvarsan, but in a fortnight the patient was as bad as ever. A second dose apparently did little good, and gave rise to symptoms of arsenical poisoning.

Dr. Ritchie also exhibited, for Dr. Gulland, a case of Stokes-Adams syndrome with apparently permanent heart-block.

DR. CHALMERS WATSON read a paper on the
FOOD REQUIREMENTS OF CHILDREN.

In connection with the feeding scheme of the Edinburgh School Board an analysis had been made of the dietary of eight children about five years of age in good circumstances—all the children of medical men. It was found that the protein intake in these children was much greater than that indicated by the Atwater standard. While the Atwater standard for a child of five was—protein 48, fat 40, carbohydrates 168 grams. = 1,220 calories, the analysis of the food of the medical children was—protein 71, fat 67, carbohydrates 198 grms. = 1,725 calories. The latter standard was probably the more reliable guide, but the importance of chemical composition *per se* could easily be over-estimated. In children of gouty and tuberculous tendency special rules applied. The adulteration of food and the effects of bleaching flour were referred to.

The following was suggested as a cheap average diet for a child:—

	Protein.	Fat.	Cost.
Breakfast—			
Oatmeal, 1 oz. ...	19.5	20	1.2d.
Treacle, 1 oz. ...			
Milk, ½ pint ...			
Bread, 2 oz. ...			
Margarine, ¼ oz. ...			
Dinner ...	30	10	1.4d.
Tea—			
Bread, ¼ lb. ...	21	19	1.2d.
Margarine, ½ oz. ...			
Milk, ½ pint ...			
	70.5	40	3.8d.

The following table shows the single-course dinners arranged for a week by the Edinburgh School Board (over 2,000 children):—

	Protein.	Fat.	Carbo- hydrate.	Cost.
Lentil soup ...	29.5	3.7	112.6	£6 3 0
Meat and potatoes ...	18.5	9.4	67.2	11 14 4
Plum pudding ...	36.4	20.2	151.4	12 12 7
Scotch broth ...	28.2	8.1	71	8 4 3
Porridge and biscuit	24.5	4.1	105.3	5 13 5
Grm.	27.1	9.3	102	1.2d.

DR. GOODALL said that he agreed with Dr. Watson that the standard suggested by Atwater's tables for a child of five was too low. The standard was 0.4 of a man at moderate work, but a healthy child of five was not content with moderate work, but did hard work as long as it could keep awake. He thought that young children should be allowed a considerable amount of red meat. He had seen marked improvement in the case of many children after farinaceous food had been largely replaced by meat.

DR. DINGWALL FORDYCE said that meat was an important item in the dietary of children under the first dentition.

DR. PORTER said that heredity and personal idiosyncrasy must be carefully studied. He thought that putrefactive changes were greater after meat than after vegetable proteins.

DR. PIRIE stated that he knew the case of two vegetarian families who had never had meat. All the children were in robust health. He thought the School Board dietaries were wanting in anything which might conserve the teeth.

DR. JAMES RITCHIE thought a great deal of the bad feeding among the lower classes was due to their ignorance of cooking and of economical purchasing. He had seen cases of tape-worm infection from the administration of raw meat. The active habits of children certainly demanded a liberal food supply, but he thought the source of the foodstuffs should be milk products and vegetable food rather than meat.

DR. W. T. RITCHIE read a paper on

VAGUS STIMULATION AND PARESIS IN THE TREATMENT OF CARDIAC IRREGULARITIES.

The inhibitory influence of the vagus was described and electro-cardiograms were shown illustrating the effects of stimulation of the vagus by digital compression in the neck. Digitalis and strophanthus acted directly on the heart and also stimulated the vagus. These drugs slowed the heart, strengthened the ventricular beats, depressed the conductivity of the auriculo-ventricular bundle, and in small doses depressed the excitability of the heart muscle in a manner comparable to vagus stimulation. All therapeutic measures which stimulate the vagus should be useful when the heart's rate is excessive. In some cases of rhythmic tachycardia due to valvular lesion and cardiac failure these measures might prove ineffective, and the same applied to some cases of paroxysmal tachycardia. The disappearance of extra systoles in cases of cardiac failure under treatment with digitalis was usually coincident with the disappearance of dyspnoea, cyanosis and oedema, and might be due to other factors than depression of excitability by vagus stimulation. In auricular fibrillation, all forms of vagus stimulation might act beneficially in virtue of their action on the auriculo-ventricular bundle. Atropin was useful in cases of partial heart-block. In *pulsus alternans* digitalis might be of service in slowing and strengthening the heart, in abolishing the alternation and in giving relief to the patient.

SPECIAL REPORTS.

THE BICENTENARY CELEBRATIONS, TRINITY COLLEGE, DUBLIN.

NOT since the Tercentenary Celebrations in Trinity College exactly twenty years ago, has academic Dublin been so gay as last week. The Celebrations opened in magnificent weather on Thursday afternoon with a reception of guests and delegates in the College Library. The ordinary somewhat sombre interior was a blaze of colour as the various visitors in full academic dress filed past the Chancellor (Lord Iveagh) and the Provost (Dr. Anthony Traill). In addition to the guests some hundreds of Dublin graduates assembled with their lady friends in the Fellows' Garden for afternoon tea.

The reception took place in the Library—a happy choice, if only on account of the fitness of the large room of the Library as a dignified setting for the notable formality. There was, however, more than that in the choice. The scene of the reception was the building nearest to the site of the old Anatomy House in which the Medical School was opened two hundred years ago. This site was, in the terms of the order setting it apart for the building of a laboratory and anatomical theatre, "at the south-east corner of ye Physic Garden"; the Physic Garden having been somewhat in the region of the present Library, extending probably for some distance into the present Fellows' Garden. The cosmopolitan element was strong in the gathering. There were delegates from Cairo, Tokyo, Tomsk, St. Petersburg, Moscow, Upsala

Helsingfors, Groningen, Paris, Stockholm, Norway, Berne, Malta, Copenhagen, Utrecht, Ghent, Liège, Geneva, Bordeaux, Vienna, Bonn and Munich, and from many of the leading cities of the United States. Then there were the Empire delegates, representing Montreal, Toronto, Melbourne, Sydney, Adelaide, Lahore and Madras. Coming back to the home countries, London was represented by its first medical Lord Mayor, Sir Thomas Crosby, and by many distinguished men representing London hospitals and institutions having their headquarters in the capital of the Empire. There were delegates from the English and Scottish provinces—Oxford and Cambridge, Liverpool, Manchester, Birmingham, Leeds, Sheffield, Newcastle, Bristol, Cardiff, York, Edinburgh, Glasgow, Aberdeen, St. Andrews and Dundee. Belfast, Cork and Galway had their official delegates, and all parts of Ireland were represented by the general assembly of medical graduates. There were representatives of the Municipality of Dublin—the Lord Mayor (Councillor Lorcan Sherlock) and Alderman Dr. M'Walter.

QUESTION OF A PERMANENT MEMORIAL.

Immediately after the reception a meeting of graduates was held in the Examination Hall, Trinity College, in the afternoon, to consider the establishment of a permanent memorial of the Bicentenary of the Medical School. Mr. Robert Woods, ex-President of the Royal College of Surgeons in Ireland, occupied the chair. There was a large attendance.

The following resolutions were unanimously carried, the speakers being the President of the Royal College of Surgeons (Dr. Purefoy), Sir Henry Swanzy, Sir John Moore and Dr. W. R. Dawson:—

(1) "That it is desirable to establish a permanent memorial of the bicentenary of the Dublin University School of Medicine, and that for this purpose a fund be opened to be called the Bicentenary Memorial Fund."

(2) "That the duty of collecting subscriptions, and, subject to the approval of the Board of Trinity College, determining the form which the memorial shall take, be entrusted to the following Committee:—Mr. Robert Woods, Chairman; Dr. James Little, Mr. R. D. Purefoy, President R.C.S.I.; Sir Charles Ball, Sir W. Launcelotte Gubbins, K.C.B., Director-General R.A.M.C.; Sir John Moore, Sir John Lentaigne, Professor A. Macalister, Cambridge; Dr. Henry Jellett, Dr. W. S. Haughton, Dr. W. Dawson, Dr. F. W. Kidd, Dr. T. E. Gordon, Dr. T. G. Moorhead, Dr. J. Lumsden, Dr. Heaney, Dr. M. J. Bulger, Dr. T. W. Goodbody, Dr. T. R. Bradshaw, Dr. Patten and Dr. Cassidy; Dr. W. G. Harvey and Dr. R. J. Rowlette, Hon. Secretaries; Sir Henry Swanzy and Dr. S. Pringle, Hon. Treasurers."

GRADUATES' DINNER.

On Thursday evening some 400 graduates and guests sat down to dinner in the Round Room of the Mansion House, kindly lent by the Right Honourable the Lord Mayor. Unfortunately the Lord Mayor was unable to be present, but his place was taken by Mr. Andrew Beattie, D.L., *locum tenens* Lord Mayor. Mr. Beattie and the Lady Mayoress, in conjunction with Mr. Robert Woods, Chairman of the Graduates' Committee, received the guests in the Oak Room. Mr. Woods subsequently presided at the dinner. To his right sat:—

The Lord Lieutenant, K.T.; the Provost, Right Hon. Michael Cox, P.C.; Professor Sir William Osler, Bart., Regius Professor; Professor James Little, Regius Professor; Count Morner (Stockholm), Sir Thomas Bartlow, Bart., P.R.C.S. (England); Professor Henri Hartmann (Paris), G. A. Berry, P.R.C.S. (Ed.); Professor Ernest Fuchs (Vienna), Sir Henry Morris, Bart., Sir Hawtrey Benson, P.R.C.P.I.; Professor Thayer (Baltimore), Sir Henry Swanzy, Professor Allvar Gullstrand (Upsala), Sir J. Halliday Croom, Professor J. G. Adams, F.R.S. (Montreal); Professor Francis Gotch, F.R.S.; Sir William Whitla, Professor Johan Nicolaysen (Norway), Sir F. H. Champneys, Bart., Sir J. M'Fadyean, Professor Faber (Copenhagen), Sir Malcolm Morris, K.C.V.O.; Professor R. von Wettstein (Vienna), and the Rev. Dr. Mahaffy.

The following gentlemen sat to the left of the Chairman:—

Councillor A. Beattie (*locum tenens* Lord Mayor); the Lord Mayor of London, Right Hon. Jonathan Hogg, P.C.; Professor Howard Marsh (Master Downing College), Professor Sir Charles B. Ball, Bart., Regius Professor; Professor Maximow (St. Petersburg), Sir Rickman Godlee, Bart., P.R.C.S. (England); Provost Edgar Smith (Philadelphia), Surgeon-General Sir Launcelotte Gubbins, K.C.B., Director-General R.A.M.C.; R. D. Purefoy, P.R.C.S.I.; Sir William Macewen, F.R.S., Prof. Hans Meyer (Vienna), J. A. Adams, P.F.P.S. (Glasgow); Professor Robert Saundby, Pres. Brit. Med. Assoc.; Professor Hans Leo (Bonn), Professor R. W. Reid, Professor A. F. Dixon, Professor R. D. Thane, Professor Blanchard (Paris), Professor Langley, F.R.S.; Sir John Ross of Bladensburg, K.C.B.; Right Hon. the Recorder, P.C.; W. A. Jamieson, Vice-Pres., R.C.P., Edin.; and Sir A. Pearce Gould, K.C.V.O.

The other guests were accommodated at seven long tables on the main floor, Dr. R. J. Rowlette, Dr. Seton Pringle and Dr. W. G. Harvey, hon. secretaries, acting as croupiers.

During dinner the orchestral band of the Royal Irish Constabulary, under the baton of Mr. William Rafter, played a selection of music.

After dinner a number of toasts were proposed. The speakers were Mr. Robert Woods, His Excellency the Lord Lieutenant, Dr. G. A. Gibson of Edinburgh, the Provost of Trinity College, Sir William Osler of Oxford, Dr. A. C. O'Sullivan of Dublin, the Lord Mayor of London, Dr. Blanchard of Paris, Dr. Maximow of St. Petersburg, Dr. Thayer of Baltimore, Sir Charles Ball of Dublin, and the Lord Mayor *locum tenens* of Dublin. Unfortunately the greater part of the excellent musical programme had to be squeezed out, owing to the length of the toast list. The arrangements for the dinner were excellent.

While the guests of the School of Medicine were entertained to a banquet at the Mansion House, the Ladies' Committee held a reception at Trinity Hall, where the visitors were all ladies, and no one could say it was not a very pleasant party. All the hostesses in town brought their guests, and a happy opportunity was given of welcoming the distinguished foreigners to Dublin. Lady Hawtrey Benson and Mrs. Lecky, Lady Ball, and Mrs. Robert Woods received the guests in the handsome drawing-room, and Miss Walton's band played on the gallery.

HONORARY FELLOWSHIPS AT THE ROYAL COLLEGE OF SURGEONS.

A meeting of the Royal College of Surgeons was held for the purpose of conferring the Honorary Fellowship of the College upon the following:—

Professor Irving Heward Cameron, LL.D., F.R.C.S. (Toronto); Mr. Robert Jones, F.R.C.S. (Liverpool); Sir William Macewen, D.Sc., LL.D., F.R.S. (Glasgow); Sir Henry Morris, Bart., F.R.C.S. (London).

The President, Mr. R. Dancer Purefoy, M.D., presided.

The Honorary Fellows were presented by Mr. Conway Dwyer, Vice-President, and Sir Charles Cameron, Hon. Secretary of the College.

RECEPTION OF ADDRESSES.

On Friday, 5th, proceedings opened with the unveiling of the memorial stone to Dr. John Stearne, founder of the College of Physicians, by the Provost, and an address by the Rev. J. P. Mahaffy, C.V.O.

Then followed the central ceremony of the Festival—the reception of congratulatory addresses by the Chancellor and Provost. Representatives of the following bodies in turn ascended the dais, and presented addresses, in most cases beautifully decorated:—

Japan.—University of Kyoto; University of Tokio.
Russia.—University of Tomsk; St. Petersburg, Imperial Institute of Experimental Medicine; Imperial Clinical Institute of the Grand Duchess Helena Pavlova; Imperial Military Academy in St. Petersburg; Women's Medical Institute St. Petersburg; University of Moscow.

Finland.—University of Helsingfors.

Austria.—University of Vienna.
 Egypt.—Cairo, Medical School.
 Switzerland.—Geneva University.
 Belgium.—University of Ghent.
 Holland.—University of Gröningen.
 Sweden.—University of Upsala; Swedish Academy of Sciences, Upsala; Stockholm, The Medico-Chirurgisches Institute; Royal Swedish Academy of Sciences, Stockholm.
 Norway.—Christiania, Royal Fredicks University.
 Denmark.—Copenhagen University.
 France.—University of Bordeaux; University of Paris; Academy of Medicine, Paris.
 United States of America.—Ann Arbor University of Michigan; Harvard University; University of Pennsylvania.
 Canada.—McGill University, Montreal; University of Manitoba, Winnipeg; Queen's University, Kingston, Ontario; University of Toronto; Royal Society of Canada; School of Medicine and Surgery, Laval Medical Faculty in Montreal.
 India.—University of the Punjab.
 Australia.—University of Melbourne; University of Sydney.

England.—University of Oxford; University of Cambridge; Royal College of Physicians; Royal College of Surgeons; London University; Society of Apothecaries; Victoria University of Manchester; Liverpool University, Faculty of Medicine; Newcastle-on-Tyne, Medical College; Birmingham University; University of Durham; University of Sheffield; University of Leeds; University of Bristol; Physiological Society; Association of Physicians of Great Britain and Ireland; Royal Veterinary College of London; The Hunterian Society; General Medical Council; Royal Society of Medicine; British Medical Association; British Dental Association; Royal Institute of Public Health; University College Hospital, Medical School, London; King's College Hospital, Medical School, London; St. Bartholomew's Hospital, Medical School; Guy's Hospital, Medical School; St. George's Hospital, Medical School; Middlesex Hospital, Medical School; Charing Cross Hospital; Royal Free Hospital School of Medicine for Women.

Scotland.—Edinburgh University; Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; University of Glasgow; Royal Faculty of Physicians and Surgeons, Glasgow; University of Aberdeen; St. Andrews University; University College, Dundee; Royal Society of Edinburgh.

Ireland.—Royal Irish Academy; Royal College of Surgeons in Ireland; National University of Ireland; Queen's University, Belfast; University College, Dublin; Royal Dublin Society; Royal Academy of Medicine in Ireland; Royal Veterinary College of Ireland.

An interesting point was that in many cases the delegates were graduates of Dublin, who now occupy important positions in other learned bodies. Thus, the following were represented by old Trinity men:—Cairo by Dr. H. P. Keatinge, Cambridge by Professor Macalister, Victoria by Dr. F. W. Lamb, Liverpool by Dr. F. R. Bradshaw and Dr. A. A. Mussen, Newcastle-on-Tyne by Professor Rankin Lyle, Durham by Professor David Drummond, Sheffield by Professor C. J. Patem, St. Andrews by Professor W. R. Scott, the Royal College of Surgeons in Ireland by Dr. R. D. Purefoy and Mr. Robert Woods, the National University of Ireland by Sir Christopher Nixon, the Royal Dublin Society by Dr. J. M. Pursel, and the Royal Academy of Medicine in Ireland by Professor J. A. Scott. Many of the graduates of Dublin were delegates of bodies which did not present addresses.

When all the other delegates had handed in the respective addresses Professor Dixon read a further list of bodies not represented:—The Universities of Bologna, Lund, Montpellier, Munich, Budapest, Innsbruck, Leipzig, Giessen, Tübingen, Königsberg, Lausanne, Naples, Berne, Bohemian University, Prague, and the German University, Prague, and the Royal Academy of Medicine. These had sent addresses or congratulatory letters or telegrams, conveying good wishes for the future of the Medical

School of Trinity College, and regrets at being unable to be personally represented at the ceremony.

On Friday afternoon the Chancellor of the University, Lord Iveagh, opened his beautiful gardens in St. Stephen's Green to the various guests and a large company. His Excellency the Lord Lieutenant was among those who attended the garden party. The gardens are singularly beautiful and charmingly laid out, and, for a town garden, are remarkably extensive. Lord Iveagh has, with characteristic generosity, presented a strip at one side of the gardens to the University College, Dublin, as a site for their new buildings.

DRAMATIC PERFORMANCE OF "SHE STOOPS TO CONQUER."

On Friday evening the Dublin University Dramatic Society gave an amateur performance of "She Stoops to Conquer" in the Queen's Theatre. The choice of a play was singularly appropriate. Oliver Goldsmith was a student of Trinity College, and later a member of our profession. The members of the Dramatic Society rose to the dignity of their task. Mr. Pigot, in particular, who played "Tony Lumpkin," showed a sense of fun, as well as a minute study of his part, which rendered his presence on the stage a constant joy. But every member of the caste threw himself into his part with so much verve and restraint that the play held the house from the rise of the curtain to the fall.

Before the first Act, an ode for the occasion, written by Mr. Oliver St. John Gagarty, F.R.C.S.I., was read by Dr. R. G. Tyrrell. Mr. Gagarty is well known as a writer of light verse, but in his Bicentenary Ode he rose to a high dignity, lightened here and there by soft touches of humour.

All the guests attended in full academic dress and the house was a blaze of colour, which must have been singularly inspiring to the actors. After the play many of the visitors attended the Trinity Week Dance, held by the students the same night.

VISIT TO THE SCHOOL OF MEDICINE.

Proceedings opened early on Saturday with a visit to the Medical School, where visitors had an opportunity of inspecting the interesting historical exhibition arranged by Dr. Kirkpatrick. There were portraits of many of the men most famous in the history of the school—Robinson, the two Stokes, Graves and others; plans of the College and maps of Dublin at different eras; class-rolls of Macartney's time, and many other objects of the greatest interest.

MEMORIAL BRONZE TO DR. D. J. CUNNINGHAM.

The task of unveiling a bronze memorial erected in the School of Anatomy by the piety of his pupils to the late Daniel John Cunningham was entrusted to Dr. James Little, Regius Professor of Physic. Cunningham was for some twenty years Professor of Anatomy in Dublin, and it was here that his best work was done. The bronze is a portrait in profile by Mr. Oliver Sheppard, D.H.A., who, with great skill has succeeded in reproducing Cunningham's remarkable luminosity of countenance.

PROCESSION TO THE ROYAL COLLEGE OF PHYSICIANS.

Immediately after the unveiling a procession was formed in the College Park, which proceeded by way of College Green and Nassau Street to the Royal College of Physicians. In front marched the Trinity College contingent of the Officers' Training Corps, with its band. Then came the Fellows of the College of Physicians with the mace of the College. Next came the medical students of Trinity College, medical graduates, guests and delegates, and finally the Chancellor and Provost, with the University mace.

On arrival at the College of Physicians, the delegates and guests were received by Sir Hawtree Benson, President, and the Fellows of the College. The reception over, a large company assembled in the large hall, where the ceremony of conferring Honorary Fellowships was held.

The following is the list of Honorary Fellows elected on the occasion:—

Norman Moore, M.D., Sir David McVail, F.F.P.S.,

Glasgow; James Mackenzie, M.D., London; George A. Gibson, M.D., Edinburgh; J. Mitchell Bruce, M.D., London; Sir Thomas Barlow, Bart., M.D.; Robert Saundby, M.B., Birmingham; Professor Thayer, Baltimore.

The President of the Royal Academy of Medicine then conferred Honorary Fellowship of the Academy on the following:—

Professor David Drummond, Newcastle-on-Tyne; Professor Kund Faber, Copenhagen; Professor Howard Marsh, Cambridge; Professor Johan Nicolaysen, Christiania; Professor V. V. Stroganoff, St. Petersburg; Sir George Savage, London; Professor Hans Leo Bonn; Dr. G. A. Berry, Edinburgh; Professor A. C. F. Eternod, Geneva; Professor Sims Woodhead, Cambridge; Professor Anderson Stewart, Sydney; Dr. H. P. Keatinge, Cairo.

CONFERRING OF HONORARY DEGREES.

In the afternoon was the ceremony of Conferring Honorary Degrees by the University. The list of recipients has already been published. The candidates were presented by Dr. T. C. Pursee, Public Orator, in Latin oratories.

DINNER IN THE COLLEGE HALL.

In the evening the Provost and Senior Fellows entertained the entire company of guests in the College Hall. Several toasts were proposed, the speakers being the Provost, Rev. J. P. Mahaffy, His Excellency the Lord Lieutenant, Dr. James Little, Professor Gullstrand of Upsala, Professor Leo, of Bonn, Principal Peterson of Montreal, Sir Thomas Barlow, Professor Starling, and Professor Dixon.

So ended three days of a remarkable celebration. The arrangements were excellent in every detail, and reflected great credit on everyone concerned, and chiefly on the Honorary Secretary, Professor A. F. Dixon. The weather was perfect, dry and cool.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 6th, 1912.

At the Hufelandische Gesellschaft, Hr. Koblack discussed the subject,

THE TREATMENT OF SEPTIC ABORTION.

He said that in his opinion the fact that there was scarcely any diminution in the mortality from child-birth was due mainly to the frequency of infection after intentional interruption of pregnancy. Physicians were not called upon to discuss the great social question of the prevention of criminal abortion, but it was their duty to point out that not only beings coming into existence but large numbers of mothers lost their lives through it.

Their manifest aim in the treatment of septic abortion was twofold—a prophylactic, not to spread the germs any further into the system; and a therapeutical to combat the infection to the best of their ability. All their striving could not, however, always be successful.

For the fulfilling of the first indication, Winter had proposed that before removing the contents of the uterus in a case of abortion, the germs in the vagina should be examined, and if the most toxic germs were present, the hæmolytic streptococci, the clearing out of the uterus should be left entirely to the contractions of the uterus to effect, so long as dangerous hæmorrhage did not compel manual interference, as it had been shown that such clearing out would force some of the bacteria into the blood tract. Against this, however, Schottmüller had objected that by this delay the condition would be made worse, as the infective bacteria would have all the more time to penetrate into the tissues.

The speaker must take his stand alongside Schottmüller as regarded this. He would, moreover, emphasise two points. In common with other investigators, they had found in the Virchow Hospital that

germs found their way into the blood current, not only when the uterus was cleared out manually, but also after spontaneous clearing out. It was, moreover, certain that not only the hæmolytic streptococci were the cause of fatal infection in childbed, but also a number of other germs—staphylococci, coli bacilli, and non-hæmolytic streptococci. For these reasons it was not necessary in practice to obtain cultivations of the vaginal germs. (The speaker here showed both aerobic and anaerobic cultures of germs of puerperal infection.)

For the prevention of the further spread of germs into the system it was above all absolutely necessary to avoid injury of the walls of the uterus. This, however, was impossible when the much-beloved curette was made use of. Penetration of the uterine wall with this instrument was not an infrequent occurrence, yet the instrument must perforate the uterus when the decomposition had reached a certain stage. (Here a uterus was shown the fundus of which was quite soft.) Perforation through the vaginal arch behind the uterus was criminal, but an instrument in scraping out the uterus must break through. In one similar case a portion of the foetus found its way into the abdominal cavity, but the life of the patient was saved by timely laparotomy. (Foetal parts of the case handed round; they were the head and thorax.) Another patient was admitted into hospital with part of a Bozemann catheter sticking through the uterine wall. The weapon was removed after splitting up the wall of the uterus and the patient recovered.

In determining the question of blame in such cases the condition of the uterine wall must always be borne in mind. In one case a five-months foetus was expelled spontaneously before their eyes, after which the patient collapsed. The abdomen was opened at once, when a hole was found in the uterus. The patient recovered after total extirpation of the organ. It was not only in consideration of the danger of inflicting gross injury that he would utter a warning against the use of the curette, but also in the knowledge that the instrument caused a large number of small wounds in the uterus through which bacteria could enter the blood channels. When the remains of an abortion had been separated from the uterus by the finger, and then could not be withdrawn through the narrow cervix, they might be removed by the large dull curette or by forceps adapted to the purpose.

As regarded the surgical treatment of puerperal sepsis he would only remark generally that they ought not to follow up the enemy by the track through which he effected entrance, by washing out, cauterisations and scrapings, but they must get in advance of the infection, and after opening the abdomen remove the chief centre or, if necessary, the whole of the infected area.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

APPOINTMENT OF DR. MILNE TO THE PROFESSORSHIP OF KANSAS UNIVERSITY.—Dr. Lindsay S. Milne who, a few years ago, was assistant to Professor Greenfield, and held a number of resident posts in the Edinburgh hospitals, and who has for the past two years been senior pathologist to the Russell Sage Institute, New York, has been offered, and has accepted, the post of Professorship of Medicine in the University of Kansas, Kansas City, U.S.A. Dr. Milne was extremely popular among his colleagues in Edinburgh, and we all wish him well in his new office.

ROYAL INFIRMARY, EDINBURGH.—APPOINTMENT.—Mr. D. B. P. Wilkie, F.R.C.S.Ed., has been appointed Assistant Surgeon to this Institution. There were seven candidates for the post.

BALDORAN INSTITUTION FOR THE FEEBLE-MINDED.—The first change chronicled in its annual report is a euphemistic change in the name of the institution. Henceforth the term "Feeble-minded"

replaces that of "Imbecile Children." The change is altogether for the better, not only from the point of view of humanity, but for the sake of accuracy, for the Institution is primarily a school for the huge middle-class of feeble-minded children who can now be taught as other children. The idiot is too bad for such an institution, and the merely backward child too good. There have been admitted 52 children during the year—33 boys and 19 girls. It is regretted that the average age on admission—nine years—is higher than is desirable, and in most cases, so far as could be ascertained there had been little or no attempt at education previously. Of these children, 21 were in good, 25 in fair, 5 in indifferent, and one in bad health. Eight children suffered from paralysis, 2 were hydrocephalic, 2 had heart disease, and 3 were tuberculous. Four were cases of mongolism, and one was a cretin. During the year 19 pupils were discharged—15 boys and 4 girls. Four of these were removed after short periods of residence by the parish councils who had sent them in. A more futile waste of public money than to send children of from 5 to 8 years to an institution of this kind for periods ranging from 7 to 18 months can hardly be conceived. Of the remaining 15 children discharged, 3 were unimprovable; the other 12 had considerably improved. Notwithstanding that in Baldoran it is the sexual rather than the educational factor which determines the time of discharge, it is gratifying to learn that the average age this year was slightly over 18, and their period of residence 8½ years. How greatly the legislation foreshadowed by the Bill recently introduced is needed is shown by the report on the further history of these discharged patients. "Three children, who averaged 9 years' residence, left the home to assist in earning a livelihood or making themselves acceptable at home. Two were sent to adult asylums, and one was returned to her parents. Five were boarded out by their respective parishes, and two were placed under the care of the Inspector of Poor. Of the latter, one was a deaf mute, and probably would be transferred to an adult asylum. The lot of the other was peculiarly regrettable. He was removed by the Parish Council because he was 14—the age when normal children leave school—and shortly afterwards was committed to an asylum. The boy had done well at Baldoran, and had learned much; had he been allowed to remain another three or four years he would probably have been able to support himself, but instead he is removed "because he is fourteen," and placed in an institution where his upkeep will be more expensive than in Baldoran. Of the other children three were quiet, clean, but incapable of learning much; they were good cases for boarding out. The remaining four children are doing well—one in service, and three boarded out, and most helpful in their situations. Ten deaths occurred during the year from broncho-pneumonia, phthisis, acute pneumonia, heart failure, wasting, hydrocephalus, and epilepsy. The Commissioners in Lunacy report favourably on Baldoran, and the annual report concludes with a number of statistical tables.

NATIONAL INSURANCE ACT.—The general feeling in Edinburgh, since the Commissioners' reply to the State Sickness Insurance Committee was made public on July 5th, is that the Association should now break off negotiations, which are apparently foredoomed to failure, and can only lead to further irritation through their futility. The probability that this course will be followed is hailed with relief. The profession is fully prepared to take the necessary steps to meet the contingency of the medical benefits being suspended. They are glad to learn that the Chancellor of the Exchequer has at last discovered that the weapon with which he threatened them when he addressed the Friendly Societies in the spring of the year is a double-edged one, and that he appears now to be afraid of the consequences of putting his threat into action. In the meantime, the attempts of the Insurance Commissioners to induce medical men to join the Provisional Insurance Committees have to a very large degree failed, for only in one or two areas have their appointments been accepted.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ALEXANDRA DAY FUND AND ITS DISTRIBUTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The response of the people of London to the appeal for the hospitals recently made in the name of our revered Queen Mother has been striking and full of pathos. A large sum of money has been collected in aid of those voluntary medical charities which form a standing protest alike against the Gradgrind and the socialist tendencies of the present age of chameleon-like evolution in which we are taking part.

Now, Sir, the object of my letter is to enter a timely warning as to the distribution of the large sum of money collected on Alexandra Day. In London there are hospitals of all kinds, large and small, general and special, but all are engaged alike in relieving the wants of the suffering and in advancing the cause of medical science. It has, unhappily, come about that the King Edward and the Hospital Sunday Funds have adopted the policy of attempting to extinguish the smaller institutions. The only official recognition of the Funds in their case comes from the Metropolitan Hospital Saturday Fund, which has steadily maintained its support of small and special hospitals.

As a member of the medical staff of more than one special hospital for more years than I care to recall, I can assert that an incredible amount of good work to the community is performed year in and year out by such institutions, and that the highest scientific aims and the highest professional traditions are maintained there in spite of struggles and difficulties of which little or nothing is heard in the outer world. Therefore, let me put in a plea for those who have no powerful friends on the Distribution Committee.

I am, Sir, yours truly,

IGNOTISSIMUS.

London, W.

July 6th, 1912.

NATIONAL INSURANCE SCHEME—DOCTORS' FEES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Within the past few weeks much has been said by public speakers at Friendly Society conferences, and at political meetings, regarding the medical aspect of the Insurance Act. The remarks of many of these speakers prove that they know very little about the matter. They, however, throw much light on the insurance finances, and show clearly that the insurance funds, got as contributions from, or on behalf of, insured persons, can—if properly managed—easily afford to pay the fair and reasonable 8s. 6d. capitation fee asked for by the medical profession. I have already written on this important point, believing that, if it were clearly understood that there are sufficient funds to allow of an 8s. 6d. capitation fee, the Insurance Commissioners would readily grant it, and so end the "deplorable medical difficulty" which would never have come into being had advice been sought in the beginning from medical men qualified to give it.

A few facts taken from a mass of statistics lying before me will, I think, make my position clear, and may be useful and much needed information to many who ought to, but do not, know much about the subject. In giving statistics—which are obtained from competent Friendly Society officials—I do not go into vulgar or decimal fractions. They are given in the same simple and easily-understood style as the "9d. for 4d." statement, but with much more accuracy:—

(1) The State has already recognised 8s. 6d. per head as reasonable remuneration for the work to be done under the Insurance Act by giving that sum to the Post Office doctors, who are in every respect club-doctors.

(2) The average contribution of Friendly Society members has hitherto been 7d. per week. The State Insurance contribution for insured persons is to be 9d. per week. There are 5,000,000 Friendly Society contributors, there will be 15,000,000 Insurance contributors.

(3) The Friendly Societies have an excellent organisation, the upkeep of which—averaging 3s. 6d. per member per annum—is deducted from members' contributions, and this organisation must be kept up for behoof of their members. The Insurance Scheme has arranged to avail itself of the Friendly Societies' organisation and pay a share of the expenses which, if arranged in a businesslike manner, should be much less than 3s. 6d. per member per annum, seeing that the arrangement is a pure amalgamation whereby 15,000,000 insured persons are to be added to the 5,000,000 Friendly Society members. If contributions of 3s. 6d. from 5,000,000 have hitherto paid for the organisation, a much smaller contribution will be necessary when an additional 15,000,000 are made to contribute.

(4) The Friendly Societies have hitherto paid their doctors, on an average, 4s. per member per annum, this sum being also deducted from members' contributions. These statistics (3 and 4) show a deduction from Friendly Society members' contributions of 7s. 6d. per member per annum for management expenses and doctors' salaries.

(5) The sick benefits hitherto given by Friendly Societies are much greater than the proposed Insurance Scheme benefits as shown below:—

	Benefits from Friendly Societies (Weekly contributions 7d. from 5,000,000 Members).	Benefits from Insurance Scheme (Weekly contributions 9d. from 15,000,000 Insured Persons).
For first 26 weeks of illness ...	10s. per week	10s. per week
For second 26 weeks of illness	7s. "	Nil.
Up to end of second year of contributing ...	5s. "	Nil.
From second year up to age of 70 ...	5s. "	5s. per week
After 70, for remainder of life	5s. "	Nil.
At death of member ...	£10	Nil.
At death of member's wife ...	£5	Nil.
At death of member's child ...	£2 10s.	Nil.
To compensated cases under Compensation Act ...	Full benefits as above	Nil.

Within recent years some slight changes have been made in a few of the Friendly Society benefits given above, but as my statistics are retrospective—to show what Friendly Societies have done—those alterations do not in the least affect my argument.

(6) While Friendly Societies—as shown above—have been paying out of members' contributions—small in number and amount as compared with the contributions of insured persons—a sum equal to 7s. 6d. per member per annum for management expenses and doctors' salaries, and have been giving much greater sick benefits than the Insurance Scheme proposes to give, they have besides accumulated a reserve fund—in other words, "saved"—somewhere about £39,000,000. The "Oddfellows" alone have nearly £16,000,000 of a reserve fund.

It is hardly necessary to point out that the above statistics show clearly that the State Insurance funds, if properly managed, will be more than sufficient to pay the reasonable capitation fee of 8s. 6d. per insured person asked for by the medical profession. It is a simple calculation which may be expressed as follows: If Friendly Societies with 5,000,000 members contributing 7d. per week pay full management expenses, give greater sickness benefits, grant 4s. per member for doctor, and save, say, £39,000,000, how much can be saved under the Insurance Scheme with 15,000,000 members contributing 9d. per week and paying only a share of management expenses, and giving much less sickness benefit? With much against them as compared with the Insurance Scheme, Friendly Societies could have paid 8s. 6d. to the doctors instead of 4s., but with diminished savings.

How much easier will it be for the Insurance Scheme to pay their doctors the 8s. 6d. asked for? The State ought not to starve the doctors so as to increase its savings.

The remarks regarding doctors recently made at Friendly Society conferences by some of their officials were neither fair nor honourable. The Friendly Societies have made very good terms with the Chancellor of the Exchequer. They are relieved of a very great part of their management expenses, and relieved altogether of the doctors' salaries, so that in future they will be able to increase very largely the sick benefits to their members. They also know very well that there will be large surplus Insurance funds which they expect will be divided among themselves as "additional benefits." Hence the ungenerous and selfish feeling displayed by some of their leaders towards the medical profession, the members of which they think should be starved so that they may have larger "additional benefits."

When all is said and done, the main object of the National Insurance Scheme is to raise the standard of the national health—to reduce sickness and death—and I would seriously point out to all concerned—Friendly Societies included—that cheap medical attendance means in most cases inefficient medical attendance. If medical men are not fairly treated so as to enlist all the members of the profession on the side of the Scheme, then the main object for which it was devised will assuredly be frustrated.

To the members of the medical profession I would point out that seeing there will be ample funds to pay the 8s. 6d. fee asked for, it will be a disgraceful and disloyal act on the part of any member who refuses to join his professional brothers in insisting on this fair and reasonable fee.

Yours very truly,
ANGUS MACPHEE, M.D.

Glasgow, July 3rd, 1912.

BRONCHIAL ASTHMA—AN EXPLANATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am charitably inclined to help you, if you will let me, out of the difficulty, to which you confess in your review of my book on "Bronchial Asthma," of understanding the drift of the case of nervous asthma which I reported. If you will look again at what I have written, you will find it stated that in accordance with the prevailing custom attacks of asthma are commonly attributed to a bronchial spasm, especially if such cases are seen only in the free intervals, and if there are no organic lesions adequate to account for the functional derangement. I added, however, that if there are opportunities of observing the attacks themselves, there are some in which *no* bronchial spasm exists, but in which at the time air freely enters into and escapes from the lungs without the slightest hindrance within the bronchial tree. The case referred to was one in point, and the beneficial effect of the few whiffs of chloroform was due, as I plainly hinted, to suggestion rather than to the dynamic action of the drug.

But I have not treated of this purely nervous asthma. The form of the disease which is the subject of my book is the one in which the recurrent attacks of dyspnoea are demonstrated due to a transient endogenous obstacle in the bronchial tree; and the illustrations, which have puzzled you so much, are intended to show the nature of the obstacle and the post-mortem appearances in those circumstances.

I am, Sir, yours truly,
J. B. BERKART.

71 Wimpole Street, W.
July 4th, 1912.

OBITUARY.

SURGEON-GENERAL B. T. GIRAUD.

THE death took place last week of Surgeon-General Byng Thomas Giraud, M.D., late of the 31st Regiment, 19th Hussars, and 7th Fusiliers, of 66 Denmark Villas, Illoe, aged 76.

The deceased, who qualified as M.D.Edin., in 1857, took part in the Russian War, 1855, serving in the Baltic Expedition and at the bombardment of Sweaborg. In the China War, 1860, he was present at the action of Sinho and the storming of Tangku, and also at the operations against the Taeping rebels, China, 1862-3. In the Afghan War, 1878-80, he served during the sortie on Delh Khoja, the defence of Kandahar, and the battle of September 1st, being mentioned in despatches. During the Egyptian Expedition, 1882, he was present at the battle of Tel-el-Kebir, receiving the bronze star and being promoted to brigade-surgeon. He retired in 1883 with the honorary rank of deputy surgeon-general.

DEPUTY SURGEON-GENERAL C. B. MOSSE, C.B.

WE regret to announce the death last week at Oberland, Guernsey, of the Hon. Charles Benjamin Mosse, C.B., C.M.G., late Deputy Surgeon-General A.M.D., and for nearly 25 years Superintending Medical Officer, Colonial Medical Department, Jamaica, aged 82. The deceased, who was M.R.C.S.Eng., L.R.C.P.I., served in the expeditionary force up the River Gambia, West Africa, June, 1866, and was present at the assault and capture of the stockaded Mandingo town of Tubarolong, being mentioned in despatches. In 1867 he was promoted to staff-surgeon for "valuable services" during an epidemic of yellow fever at Bathurst. He served throughout the Ashanti War, 1873-4, being again mentioned in despatches; he was made a C.B. and received the medal with clasp. He became Superintending Medical Officer for Jamaica in June, 1896, and retired in 1904.

MEDICAL NEWS IN BRIEF.

The Edgar Allen Institute at Sheffield.

THE first general meeting of the Council of this Institute was held last week, when the following officers were elected:—Mr. W. Edgar Allen, Chairman; Mr. E. Willoughby Firth, J.P., Vice-Chairman; Mr. S. Doncaster, Hon. Treasurer; Mr. A. Harland, Hon. Secretary.

Mr. Allen, who occupied the chair, and to whose munificence the foundation and upkeep of this Medical Institute is due, expressed his great satisfaction at the work done during its first year. He stated that up to date 505 patients had received treatment, each one of whom had been recommended for treatment by a medical man, the total attendances at the Institute since the opening in July, 1911, being 22,418, the present average attendance being 111 patients daily. He explained that the treatment practised at the Institute (as described in these columns on its foundation) is new to this country, although over 200 similar institutions on the Continent are now treating thousands of patients, some of these establishments being supported by their respective Governments. In thanking the members present for their attendance, Mr. Allen hoped the good work would go on increasing, and expressed the pleasure it gave him in seeing such successful results. He added that he holds himself personally responsible for the entire expenditure during the first three years' working, unless the amounts received enable the Institute to become self-supporting. Nearly the whole of the patients at present are receiving gratuitous treatment.

Dr. R. G. Abercrombie, Medical Director of the Institute, spoke of the support and co-operation which had been given to the Institute by the medical profession of Sheffield, and pointed out the great importance of this co-operation for the utility of this institution. He expressed the opinion that the first year's work had proved to be of real benefit, especially in the after-treatment of accidents and injuries, which are so common among the industrial and mining population of Sheffield and the district.

It may be added that in July, 1911, before the opening ceremony, some ninety members of the medical profession attended and inspected the Institute, and

later on the members of the Sheffield Medico-Chirurgical Society, in about an equal number, visited the Institute, when Dr. Abercrombie demonstrated the treatment of patients, and the President of the Society expressed his satisfaction and interest, and approved of the methods of treatment employed.

A Tuberculosis Dispensary for Deptford.

THE Deptford Public Health Committee proposes to establish in that borough a tuberculosis dispensary. The estimated cost of fitting and furnishing the premises is £300, and the approximate annual expenditure for staff, rent, rates and taxes, drugs, etc., will be £700.

Royal College of Surgeons of England—Election.

ON Thursday last the annual meeting of Fellows was held to elect four members of Council in the vacancies occasioned by the retirement in rotation of Sir Frederic Eve, Sir Anthony Bowlby, and Mr. Gilbert Barling (Birmingham), and by the death of the late President, Sir Henry Butlin. The result of the poll was as follows:—

	Votes.
1. Sir Anthony Bowlby	507
2. Sir Frederic Eve	427
3. Mr. D'Arcy Power	405
4. Sir Berkeley G. A. Moynihan (Leeds) ...	394
5. Mr. Gilbert Barling	387
6. Mr. J. Ernest Lane	339
7. Mr. L. A. Dunn	255

Sir Frederic Eve and Sir Anthony Bowlby were declared re-elected, and Mr. Power and Sir Berkeley Moynihan were elected members of the Council. The poll was a heavy one, 896 Fellows recording their votes. Editorial reference to the election will be found in another column.

University of Durham.

The following candidates have passed in:—

Elementary Anatomy and Biology, Chemistry and Physics.—John Gilmour (first-class honours), Norman Braithwaite, Harry C. Broadhurst, Willmore J. Hooper, George N. Metzger, and Ralph R. Scott.

Chemistry and Physics.—John Brunwell, Dorothy E. Butcher, George A. Clark, Roy N. Craig, Mary R. Campbell, William A. Hewitson, John Horsley, Reginald Hunter, John K. R. Landells, Phyllis Marriott, Reginald S. Millar, George F. Philip, William O. Sinclair, and Kamel I. Shalaby.

Elementary Anatomy and Biology.—Stephanie Patricia L. H. Daniel, Christopher T. Helsham, Donald Henegan, Patrick Hickey, Robert B. Perrie, and William A. Tweddle.

The following candidates have passed the third examination for the degree of Bachelor of Medicine:—

Materia Medica, Pharmacology and Pharmacy, Public Health, Medical Jurisprudence, Pathology and Elementary Bacteriology.—Cyril Armstrong (with honours, second class), Ishmael G. Cummings, Charles N. Gover, Mary L. Haigh, Maurice H. de Jersey Harper, Cyril Jacobs, Robert R. Lishman, Edward R. A. Merewether, Francis Metcalfe, Ernest C. G. Parker, Ivan M. Pirrie, Kirton I. S. Smith, Charles R. Smith, and James C. Spence.

Edward Phillips passed in Public Health, Medical Jurisprudence, Pathology and Elementary Bacteriology.

Royal College of Physicians of Ireland.

THE President and Fellows of the Royal College of Physicians of Ireland, at a recent meeting, decided to confer the Honorary Fellowship of the College on Sir Thomas Barlow, Bart., K.C.V.O., M.D.Lond., President of the Royal College of Physicians of London; John Mitchell Bruce, M.D.Lond., F.R.C.P.Lond.; George Alexander Gibson, M.D.Edin., F.R.C.P.Edin.; James Mackenzie, M.D.Edin., M.R.C.P.Lond.; Sir David M'Vail, M.B.Glas., F.F.P.S.Glas.; Norman Moore, M.D.Camb., F.R.C.P.Lond.; Professor Robert Saundby, M.D.Edin., F.R.C.P.Lond., President British Medical Association; William Sydney Thayer, M.D., Harvard, Professor of Clinical Medicine, John Hopkins University, Baltimore, U.S.A.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

DR. F. C. W. (Yorks.).—One of the great advantages of the chloral is that the after-effects are practically nil, the unconsciousness which supervenes for six or eight hours after the operation sufficing to tide the patient over the usual "vomiting period." Intravenous anaesthesia is to be preferred in many cases to the ordinary method of inhalation. It is noteworthy that lung trouble is very rarely observed after anaesthetics given in this way.

"ANTI-MALARIA" is informed that chocolate-coated tablets containing tannate of quinine were imported a year or two ago in large quantity to St. Lucia, for distribution in the schools, simple directions being given to the teachers regarding the manner in which the tablets were to be given.

DR. F. P. (Suffolk).—The occurrence of the loss of the knee-jerk in pneumonia was described by the late Dr. Hughlings Jackson in 1894. The reflex usually disappears on the third or fourth day, returns about the ninth day somewhat increased, and gradually becomes normal about the end of the second week in ordinary cases. Its disappearance before the third day is said to be of bad import, while if it remain normal until the seventh day recovery may be held to be almost certain.

INQUIRER (South Hackney) will find all information about the Health Centre and Dental Clinic, which was started in 1910 in Newport, Essex, by Lady Meyer, in a pamphlet issued by Messrs. J. H. Clarke and Co., of Hight Street, Chelmsford.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 10TH.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Steuart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Dunstan). 5.30 p.m.: Eye Operations (Mr. Brooks).

THURSDAY, JULY 11TH.

OPHTHALMOLOGICAL SOCIETY (11, Cando's Street, Cavendish Square, W.).—5 p.m.: Special Meeting to Consider the Question of Amalgamation of the Ophthalmological Society of the United Kingdom with the Royal Society of Medicine. 8 p.m.: Ordinary Meeting. Card Specimens will be shown by Mr. Jessop and Mr. T. Collins. Papers:—Mr. B. James and Mr. S. Hosford: The Operative Treatment of Glaucoma. The Annual General Meeting will be held immediately after the Ordinary Meeting.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

THE NEW LONDON DERMATOLOGICAL SOCIETY (Western Skin Hospital, 46 Hampstead Road, N.W.).—4.30 p.m.: Annual Meeting: Dr. D. Walsh will show drawings illustrating the connection between cardiac disease and chronic and re-current skin affections. Clinical cases: Canities and Leucoderma (Dr. P. S. Abraham); Alopecia, nervosa et traumatica (Dr. Walsh); Dermatitis herpetiformis (Dr. Meachen), and other cases. The annual dinner will be held at 7.30 p.m. at Pagani's Restaurant, Great Portland Street, W.

Appointments.

CLARKE, CECIL, M.D., B.S.Lond., Assistant to the Superintendent of the Laboratories at the Hospital for Consumption, Brompton, S.W.

CRISP, JAMES ELLIS, M.R.C.S., L.S.A., Medical Officer to the Scattered Homes by the Chippenham (Wilts) Board of Guardians.

GLINN, E. E., M.D.Cantab., M.R.C.S., M.R.C.P.Lond., George Holt Professor of Pathology in the University of Liverpool.

TYBES, FREDERICK, M.S., F.R.C.S., appointed Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit, No. 1.

RANDOLPH, WILLIAM HENRY, L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 2 District by the Dulverton (Somerset) Board of Guardians.

ROBINSON, W. E., M.D., B.Ch.Oxon., Visiting Anaesthetist to the Royal Waterloo Hospital for Children and Women.

WOOLF, A. D., M.D. (Brux.), L.R.C.P., L.R.C.S. (Edin.), L.R.F.P. and S. (Glas.), Assistant Anaesthetist to the Prince of Wales' Hospital, Tottenham.

Vacancies.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, washing, and attendance. Applications to Medical Superintendent.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 a year, with board and lodging. Applications to Wm. H. Sands, Secretary.

West Derby Union.—Mill Road Infirmary, Liverpool.—Assistant Resident Medical Officer. Salary £125 per annum, with board, etc. Applications to Harris P. Cleaver, Clerk to the Guardians, Union Offices, Brougham Terrace, West Derby Road, Liverpool.

Borough of Hampstead.—Medical Officer of Health. Salary £600 per annum. Applications to Arthur P. Johnson, Town Clerk, Town Hall, Haverstock Hill, N.W.

Woolwich Tuberculosis Dispensary.—Assistant Medical Officer. Salary £225 per annum. Applications to Dr. Sidney Davies, Town Hall, Woolwich.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointment:—Jedburgh (Roxburgh).

House of Recovery and Fever Hospital, Dublin.—Junior Assistant Resident Medical Officer. Salary £50 per annum, and board. Applications to J. M. Day, Medical Superintendent. (See advert.)

Births.

BURSTAL.—On July 4th, at Cherwell, Staines, the wife of Edward Burstal, M.B., of a daughter.

DOTTRIDGE.—On July 4th, at Overton, Godalming, the wife of Cecil A. Dottridge, M.B., of a son.

HARMEE.—On July 6th, at 45 Weymouth Street, W., to Mr. and Mrs. Douglas Harmer, a son.

RAWES.—On July 4th, at "The Lodge," Sarisbury Green, Hants, to Dr. and Mrs. Leslie Rawes, a daughter.

THOMPSON.—On June 26th, at Wrexham Lodge, Ealing, the wife of Major F. S. Corbett Thompson, I.M.S., of a son.

TIDY.—On July 4th, at 39 Devonshire Place, W., the wife of Henry Letheby Tidy, of a son.

Marriages.

HUTCHINSON—KNOWLES.—On July 2nd, at Huyton Parish Church, Lancelot Hutchinson, M.D., to Doris, only daughter of the late Herbert Knowles, M.D., M.R.C.S., of S. Helens, and of Mrs. Knowles, Hayton.

RENSHAW—TAYLOR.—On July 4th, at St. Paul's Church, Kersal, Manchester, J. A. Knowles Renshaw, M.D., 11 St. John Street, Manchester, second son of Dr. and Mrs. Chas. J. Renshaw, Beech Hurst, Ashton-on-Mersey, to Amy, elder daughter of Mr. and Mrs. George Taylor, and niece of George H. Charlesworth, Clarendon, Kersal.

SANKEY—SAXBY.—On July 2nd, at St. Nicolas, Abingdon, Richard Harvey Sankey, M.D., of Oxford, only son of Mr. and Mrs. Heurtley Sankey, to Audrey Mary, eldest daughter of Mr. and Mrs. George Saxby, of Trickenham House, Abingdon.

WALLACE—JACKSON.—On July 6th, at St. Marylebone Parish Church, London, Cuthbert Sidney Wallace, F.R.C.S., of 26 Upper Wimpole Street, youngest son of the Rev. John Wallace, to Florence Mildred, youngest daughter of Herbert Jackson, of 4 Sussex Place, Regent's Park.

Deaths.

GILCHRIST.—On July 2nd, at Cairant, May, the beloved wife of A. W. Gilchrist, M.D., of Nice.

McKEE.—On July 3rd, Alexander Baillie McKee, M.B., of 50 Shell Road, Lewisham, London, elder son of the late Rev. T. A. McKee, D.D., of Dublin.

MOSSE.—On July 4th, at Oberland, Guernsey, Channel Isles, the Honble. Charles Benjamin Mosse, C.B., C.M.G., late Dy-Surgeon-General A.M.D., and for nearly 25 years Superintending Medical Officer, Colonial Medical Dept., Jamaica, aged 82.

SPENCER.—On July 5th, at Queen's Mansions, 54 Victoria Street, S.W., Elizabeth Gordon Lamond, wife of Surgeon-General Sir Lionel D. Spencer, K.C.B., M.D., K.H.M.

STERICKER.—On July 1st, Frederick Walter Stericker, M.D., late R.N., eldest son of the late Frederick Stericker, aged 51.

DOCTOR'S RESIDENCE.

Gordon Square, London, W.C.—To be let, one of the best houses in this favourite square; seven bed-rooms, four excellent reception-rooms, and commodious offices.—Particulars of Messrs. Edwin Fox, Bousfield, Burnetts, and Baddeley, 99 Gresham Street, City.

No. 3.

NOTES AND COMMENTS.

THE position of the medical profession in Scotland with regard to the National Insurance Act is on the whole satisfactory. In our last week's issue we hinted at sundry rifts within the lute, but their very method of revelation, namely, that of condemnation by resolution, showed that forearming was the first deliberate part of forewarning. Scotland is a land where political feeling runs high, and it cannot be expected that all members of the medical profession will be prepared at a moment's notice to place their profession behind their politics. That, at any rate, is the only construction we find ourselves able to place upon the actions of men about whose *bona fides* there is no room for doubt. We had hoped up to the last moment of going to press that a personal explanation would have reached us from those whose names have been brought forward in so pointed a manner by the resolutions, which were commented upon last week in these columns. It is to be regretted that the matter of the Insurance Act and compliance with the general wish of the majority of the profession was not made a test question before the last election of the Direct Representative upon the General Medical Council. The function of a Representative is to represent, and if he finds himself hopelessly at variance with nine-tenths (or more) of his constituents, there can be little doubt on the part of any man of ordinary sensitiveness in such things as to the next step to be taken. Until the much-to-be-desired personal explanation is forthcoming, however, it is premature to discuss that side of the question.

The Cost of the Wassermann Test. THE cost of the application of the Wassermann test for syphilis is so great as to preclude its general use. In smaller hospitals, where the services of a well-equipped laboratory and a pathologist are not available, the honorary medical staff are seriously handicapped in their endeavour to give the patients under their care the advantages of skilled modern treatment. In some instances we have known medical men pay the cost of such laboratory tests out of their own pockets, but the practice, however creditable to the humanity and generosity of the medical men concerned, must, nevertheless, be obviously limited in practice. Yet the value and the occasional necessity of the Wassermann test in every branch of medical and surgical practice, if good results are to be obtained, may be accepted as a self-evident proposition. It is in the detection, the cure and the prevention of disease an element of vast economic importance to the community. It is to the public, then, that we must look for help in this matter. Why should not that philanthropy which is willing

to provide ample funds for the investigation of cancer, and of so abstract a matter as radium-therapy, not found a Wassermann institute, to which the blood of any person could be sent for examination free of cost? Why not, forsooth, and why not—again—why not tackle syphilis?

Principles Before Office.

IN THE MEDICAL PRESS AND CIRCULAR for February 28, 1912, we commented in a leading article upon the position of lay boards with regard to the purely medical details of hospital management, with special reference to the case of the Renfrew and Clydebank Hospital. It will be remembered that Dr. W. Butchart, the then medical superintendent of the institution, had been practically forced to resign his position because he had been ordered by the board to carry out a certain mode of treatment for scarlet fever, in the efficacy of which he did not believe. As it was, the mortality at the hospital was exceptionally low and the cases did remarkably well. A certain section of the board, ignoring these obvious facts, allowed their parsimonious ideas to run away with their sense of justice or decorum, with the result that, after fifteen years of honourable service as medical superintendent, Dr. Butchart felt himself obliged to separate his connection with the hospital, rather than submit to seeing his patients subjected to what he considered an unjustifiable experiment. While sympathising with Dr. Butchart in the trying position in which he found himself, we were confident at the time that the wisdom of his action would be appreciated, not only by his colleagues in the profession, but also by the public. Subsequent events have proved the truth of our contention, for the other day Dr. Butchart was the recipient of a handsome silver casket, an illuminated address and a purse of sovereigns, at a crowded meeting of the burgh, in recognition of his sterling worth and high professional abilities. The testimonial especially mentioned the fact that during Dr. Butchart's tenure of office the mortality at the hospital was much below the average for the West of Scotland, while it assured him of the esteem in which he was held by the people of Clydebank, as well as of their undoubted faith in his professional judgment.

Lantern versus Wool Test for Colour-blindness.

DR. A. LYNCH, M.P., has done good service in asking the President of the Board of Trade in the House of Commons whether the Committee on Sight Tests have demonstrated the superiority of the lantern over the wool test for colour-blindness, and whether Dr. Edridge Green's lantern had been found satisfactory by the Admiralty. The answer was official and non-committal, but it is to be hoped that our Navy

will ultimately adopt a scientific method for testing the colour-vision of would-be sailors. It is now over twenty years since Dr. Edridge Green, as adviser to the Board of Trade, pointed out the defects of the Holmgren wool test. That authority has published reports of specific instances in which men who passed the wool test perfectly were afterwards shown by the lantern test to be hopelessly colour-blind. It is clear, therefore, that to pass men on so defective a test as that of Holmgren is to run the risk of taking into the Navy men whose physical defect in sight would be a source of constant danger. It would be greatly to the advancement of scientific medicine, and it would be also in the economic interests of the community were there more Members of Parliament possessed of professional training and zeal such as those which characterise Dr. Lynch.

LEADING ARTICLES.

THE INSURANCE ACT AND THE MEDICAL PROFESSION.

MONDAY last, July 15th, witnessed the coming into operation of the National Insurance Act. The leading actor in the drama, the medical profession, was conspicuous only by absence, a situation that, for grotesque departure from precedent, was surely never surpassed even in the strange and shifting kaleidoscope of domestic politics. To play Hamlet without the Dane in this fashion is to attempt a feat worthy of the highest political genius—or temerity—and the result of a long tangle of negotiations leaves the issue, even at the eleventh hour, yet in the balance. The latest move on the part of the Chancellor of the Exchequer was to obtain a report from Sir William Plender, a well-known accountant, as to the incomes of medical men in Darlington, Darwen, Dundee, Norwich and St. Albans. The general result places the average medical income at 4s. 2d. per head of population, a figure that covered all medical and surgical attendance and (except in the case of Dundee) medicine. The *Daily News*, whose reasoning from figures is usually of Machiavellian subtlety, says, in its issue of July 13th, that Mr. Lloyd George offers the doctors 8s. 6d. per head. The sum is made up of 4s. 6d. capitation grant, 1s. 6d. for drugs and 2s. 6d. for extras. If that sum has been definitely proposed per head of insured persons under the Act, and the further conditions of free choice of doctors and adequate medical representation secured, it is difficult to see any reasonable ground for further differences between the Government and the medical profession. But surely there must be some little rift in the actuarial lute wherewith the *Daily News* statistician charms and convinces his many readers. On the 13th instant the Chancellor declared that he would not give an eleven shillings grant—an utterance which is less definite than that of the *Daily News*. The medical profession prefers to cling to certain conclusions which it has elaborated with much exercising of the spirit, a course to which it has been prompted by the belief that its material pro-

sperty was grievously imperilled by the pressgang tactics of Mr. Lloyd George. It seems almost incredible that a serious politician of the front rank should calmly arrange to arrogate the services of a great professional body without having first carefully investigated the economics of the position from every point of view, and without having ascertained the views of the profession at first hand. Hence we have the diverting spectacle of a Cabinet Minister of first rank, within a few days of the coming into operation of an Act, conducting an actuarial investigation which should have been made at a preliminary stage of the proceedings. The matter has now well-nigh passed out of the stages of negotiation. The last Fabian tactic of Sir William Plender's inquiry has not advanced matters materially, although it has successfully postponed the day of final settlement. If a definite offer of 8s. 6d. *per caput* of insured persons is offered, should the medical profession not be at once put in possession of the fact? The *Daily News* is generally supposed to be more or less in the confidence of the Chancellor of the Exchequer. Will Mr. Lloyd George say "yes" or "no" to the assertion contained in its issue of July 13th to the effect that 8s. 6d. *per caput* of insured persons is offered to the medical profession? Failing the immediate announcement of some such definite sum, we repeat the advice we have given of late on various occasions in the columns of THE MEDICAL PRESS AND CIRCULAR, namely, for every medical practitioner in the United Kingdom to join a public medical service organisation. Further, we advise medical men to take up an active campaign against the present Government, regardless of their personal political views. The Government has flouted medical opinion, it has carried on negotiations which have been subtle, unconvincing and inconclusive, it has made appointments of medical men that have been received with universal abhorrence by the medical profession, and now, with the Act in operation, medical men still find their just and clearly-defined demands staved off with plausible sophistries and unmeaning generalities. The method that is likely to be most effectual as a means of self-defence is to assume the weapons of political aggression, and to convert the medical profession into a solid opposing army. The only way to meet this sort of injustice is, in our opinion, by organised political protest. There need be no question as to the ability of the Insurance Commissioners to pay the sum of 8s. 6d. per head, a point that was pretty conclusively shown by our correspondent, Dr. Macphee, of Glasgow, in our issue of July 10th. In conclusion, a passage may be quoted from that gentleman's most admirable communication:—"When all is said and done," he writes, "the main object of the National Insurance scheme is to raise the standard of the national health—to reduce sickness and death—and I would seriously point out to all concerned—Friendly Societies included—that cheap medical attendance means in most cases inefficient medical

attendance. If medical men are not fairly treated, so as to enlist all the members of the profession on the side of the scheme, then the main object for which it was devised will assuredly be frustrated."

THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM AND THE ROYAL SOCIETY OF MEDICINE.

OF the existing special medical societies in London, the only one which has failed to become a unit of the Royal Society of Medicine is the Ophthalmological Society of the United Kingdom. All the other societies have fallen into line, have recognised the wisdom of the step, and are now happily profiting by this valuable scheme of amalgamation and co-operation. But for some reason the Ophthalmological have adopted a negative policy and have held aloof, for which no substantial explanation has ever been forthcoming. When, some years ago, the project was first brought under the notice of the members, absolute rejection was its fate. Then a lukewarm feeling in its favour led to the matter being subsequently reopened, but again with the result that those who desired the amalgamation were outvoted by those who did not. At length, after meandering about in the wilderness of refusal, during something less than the traditional period of forty years, a final agreement has been reached, by which the Society has virtually committed an act of suicide. Some short time ago the Council summoned a special meeting of the members, to be held on July 11th—last Thursday. The object of the meeting was expressly to discuss a resolution supported by the Council favouring the scheme of amalgamation, urging in support thereof the many cogent and unanswerable reasons which rendered the step expedient. To this resolution an amendment was subsequently issued to the members prior to the meeting; the amendment being to the effect that the Council be requested to consider the advisability of so altering the rules that all the meetings of the Society may be held each year during the course of one week, as is done by other National Ophthalmological Societies. At the meeting last week, which took place as arranged, this amendment was agreed to. But at the same time, it was understood that the members of the Society were left free to join an Ophthalmological Section of the Royal Society of Medicine, should one be formed. The inevitable has happened with that speed which characterises up-to-date organisations and enterprises full of movement and life. Two days ago the Council of the Royal Society of Medicine agreed to the formation of an Ophthalmological Section, and steps are already being taken to give effect to that decision. Thus the matter so far stands, and it is of interest to ask: How does it affect the Ophthalmological Society? The situation resolves itself naturally into one of the commonplace description of competition. On the one hand there will be an Ophthalmological Section, full of activity and life, rejoicing possibly in its new and

attractive environment, grafted upon a parent stem having many other sturdy branches, all flourishing, and bringing forth fruit under the central stimulus; and on the other, a stunted Society, whose period of vitality is limited to one week in the year. It may be doubted whether such attributes would suffice to sustain the existence of a Society devoted to the advancement of so special a science as that of ophthalmology. An annual congress may be a good adjunct to a Society, but it can never be the sole crutch upon which a society, whatever its nature, could be supported. Moreover, what inducement does this congress offer to the members of the Ophthalmological Society of the United Kingdom to continue their membership? Viewed from the aspect of the lowest ground—that of subscribing to it—the inducement is rather in the other direction; for by joining the Royal Society of Medicine, the members will be able to credit themselves with their annual subscription to the Ophthalmological Society, besides having in hand the other valuable advantages which Fellowship of the Royal Society of Medicine confers. Nevertheless, we are prepared to concede the expediency of the idea of organising a British Ophthalmological Congress. The idea is distinctly a good one. Nothing of the kind in this country has hitherto been attempted, and it would be a step in the right direction to undertake the enterprise. But its organisation would necessarily have to be on different lines from those proposed, and the best method of carrying the scheme into effect would be by utilising to the full the facilities available after the formation of the Ophthalmological Section of the Royal Society of Medicine.

CURRENT TOPICS.

The Treatment of Tuberculosis under the National Insurance Act.

IN a circular letter from the Local Government Board dated July 6th, 1912, *i.e.*, nine days before the National Insurance Act came into operation and sanatorium benefits began, it is stated that the Board trust that the services of the Medical Officers of Health will be available for the purpose of making arrangements with the Insurance Committees for the treatment of insured persons recommended for sanatorium benefit. It is earnestly to be hoped that the various county and borough councils have already prepared their schemes for this treatment and that there may be no lack of co-operation with the sanitary authorities with regard to the working of the County Scheme. According to section 16 (1) of the National Insurance Act, it is necessary that the approval of the Local Government Board should be given to any sanatorium, dispensary, or other institution in which insured persons are to be treated. As regards domiciliary treatment of cases of tuberculosis under the National Insurance Act, the Board and the Insurance Commissioners concur in thinking it desirable that this should be carried out as far as practicable by general practitioners acting in consultation with the tuberculosis officers of the area, or other approved adviser, due regard being had to the importance of the hygienic conditions

of the home in all cases. The Board wish again to direct attention to the paragraph in their circular letter of May 14th last as to the appointment of suitably qualified and experienced men for the senior appointments in connection with dispensaries and sanatoria, and in this connection they would draw attention to the recommendation on this part of the subject in the Interim Report of the Departmental Committee on Tuberculosis to the effect that such officers should preferably be not under the age of twenty-five and that they should have had at least six months' experience of resident appointments in a general hospital, as well as in an institution for the special treatment of tuberculosis.

An Appeal in Aid of Tropical Medicine.

A COMMITTEE has been recently formed at the request of the Secretary of State for the Colonies to raise funds for the extension and development of the work of the London School of Tropical Medicine. Mr. Austen Chamberlain is the Chairman, and in the course of his appeal it is stated that £100,000 is required to provide an adequate endowment fund, to make additions to the laboratories and buildings for the accommodation of the growing number of students, to provide for the prosecution of research, and to establish a small nursing home for civilians who cannot afford to procure for themselves the special medical and surgical treatment and nursing required in these special branches of disease. There should be little need to press the claims of this institution before the public, for the manner in which great and important discoveries, emanating from this school, have not only been the means of saving valuable lives, but have also literally revolutionised the conditions of existence in certain tropical regions, is now common knowledge. The warm interest always taken in the London School of Tropical Medicine by Mr. J. Chamberlain, under whose auspices it was founded in 1899, should suffice to stimulate the philanthropic instincts of every loyal British subject. Already over £15,000 has been collected. Subscriptions may be sent to the Lord Mayor's Fund, the Secretary of the London School of Tropical Medicine, Connaught Road, E., or Mr. Austen Chamberlain himself, who will preside at a meeting of the Committee to be held at the Foreign Office to-day, July 17th, at 4 o'clock.

The Sanatorium Benefit.

IN the fight that is being made by the medical profession for proper conditions of service under the Insurance Act, it is essential that unanimity should be preserved. To do this we must be careful that we do not raise unnecessary grounds of quarrel. Up to the present our only ground of quarrel has been with the proposed administration of the medical benefit. The sanatorium benefit presents no obnoxious features, and if it is to prove at once useful to the public and acceptable to the medical profession, it is of the utmost importance that the schemes for its administration should be framed in accordance with medical opinion. The action of the State Insurance Committee of the British Medical Association in declaring war on the sanatorium benefit seems to us, therefore, a mistake both in tactics and in policy. It is likely to alienate the sympathy of the public, which up to the present has been with the profession. It is sure to create dissension in our own ranks. It will result in the starting on wrong lines of what will be one of the most important departments of the public health work in the country. We trust that the representative body of the Association, at its meeting next week, will reverse the policy of the

State Sickness Insurance Committee, and see that our just quarrel is kept within its proper limits.

Larvicides and Malaria.

IN the campaign against malaria, great reliance has been placed on the use of so-called larvicides, and in particular on kerosene oil. Nevertheless, in spite of arduous work, the results have been often disappointing. In a paper read recently before the Asiatic Society of Bengal, Surgeon-Captain F. F. MacCabe subjects the methods of the orthodox campaign to a severe criticism. In a number of experiments, performed some in the laboratory and some in the field, he found that kerosene had little action as a larvicide, but that it completely cleared pools of the fresh-water snail, which normally destroys many larvæ. Dr. MacCabe made experiments with various disinfectants, but the only preparation he found of practical use was a mixture of chloride of lime and common paraffin oil. This seemed to have a rapidly destructive effect on mosquito larvæ. More important than the use of any larvicide, however, is the clearing of waste water and the draining of pools. As an accessory to the use of paraffin and chloride of lime, he found an electric current of help. The current he employed was a low-tension current of two hundred and twenty volts.

Hospital Accommodation for the Dying.

A CURIOUS discussion has recently taken place at the Academy of Medicine in Paris with regard to an innovation which is likely to be introduced shortly into the new hospital at Lyons in the shape of separate rooms for patients who are in a hopeless condition. The idea of providing special apartments for moribund patients in general hospitals is utterly repugnant to public feeling in this country, for the small compensation of extra privacy would be immensely outweighed by the depressant effect that would be inevitably produced upon the other inmates by the knowledge that one of their number was being transferred to a place where all hope of life was presumably abandoned. The careful screening of the dying in a general ward of a hospital is done more in the interests of the other patients, so that those in the adjacent beds may be spared witnessing painful scenes. The added privacy thus secured is also a tribute to the feelings of the relatives and friends who are entitled to some consideration in their times of grief and distress. It is the greatest mistake in the world to associate any particular bed in the ward with a "bad case," as is sometimes involuntarily done by students and nurses, or to give expression to the absurd superstition that its occupant has "never been known to recover." A private room or ward for the reception of grave cases upon admission is a good thing where funds permit, but the provision of rooms whither patients are to be transferred as soon as their condition is adjudged hopeless is, in our opinion, cruel, unnecessary, and absolutely unjustifiable.

Inebriety and Art.

ONE of the penalties associated with the possession of the artistic temperament is an increased susceptibility to emotional stimuli. Indeed, it is difficult to conceive an individual having the sensitive organisation characteristic of this type who is not more or less profoundly affected by sense-impressions or psychical forces projecting themselves within his sphere of consciousness. It seems that some degree of nervous instability is the necessary accompaniment of all artists worthy of the name, *i.e.*, those whose work is stamped with the unmistakable brand of genius.

To such natures, especially if their power of self-control be not too strong, the temptation to have recourse to artificial stimuli in order to increase their productive power is very great. That these agencies may, and do, have such effects at first is well known, but the quality of the work speedily suffers until the hapless victim is driven to the use of abnormal or perverted stimuli in order to obtain any inspirations at all. The subject was ably dealt with at the last meeting of the Society for the Study of Inebriety, by Dr. T. B. Hyslop, who was of the opinion that many of the so-called "up-to-date" hysterical attempts to revolutionise art, music, and literature were due to over-indulgence in the sensuously beautiful and the consequent endeavour to stimulate the exhausted faculties by alcohol or some other drug. The higher the nervous organisation and the finer the intellectual or emotional temperament the less is the tolerance of stimuli of this nature.

The Medical Advisers of the Colonial Office

THE announcement of the retirement of Sir Patrick Manson, M.D., K.C.M.G., F.R.S., from the post of Medical Adviser to the Colonial Office in London, which will take place next month, recalls one of the greatest triumphs of preventive and tropical medicine during the last century. His enunciation of the hypothesis, afterwards confirmed by Sir Ronald Ross, that the mosquito is the host of the malarial parasite during one stage of its existence may be said to have laid the groundwork of research in relation to the mode of transmission of certain tropical diseases. The medical profession will be especially gratified at the further mark of royal favour recently bestowed by the King upon one of its most distinguished members in the shape of his appointment to be a Knight Grand Cross of the Order of St. Michael and St. George. It has been found necessary to divide the duties hitherto discharged by Sir Patrick Manson, and the Secretary of State for the Colonies has appointed Sir J. Rose Bradford, M.D., K.C.M.G., F.R.S., to be Senior Medical Adviser, and Mr. C. W. Daniel, M.B., M.R.C.P., to be Junior Medical Adviser to the Colonial Office in London, while Mr. W. T. Prout, C.M.G., M.B., will be Medical Adviser in Liverpool. These appointments, which will take effect from the date of Sir Patrick Manson's retirement, will be welcomed by those who know anything about the high scientific attainments of their holders. A happier choice could hardly have been made, for in their new counsellors the Colonial Office has secured the aid of physicians of ripe judgment and practical experience in their respective spheres.

PERSONAL.

H.M. THE KING has been pleased to give directions for the appointment of Sir Patrick Manson, LL.D., M.D., F.R.S., K.C.M.G., Medical Officer to the Colonial Office, to be a Knight Grand Cross of the Order of St. Michael and St. George in recognition of his eminent services in connection with the investigation of the cause and cure of tropical disease.

DR. A. J. CLARK has been appointed Demonstrator of Pharmacology at King's College, London.

DR. W. A. T. LIND, M.D. (Melb.), has been appointed Pathologist and Neurologist to the Department of Lunacy, Victoria.

MR. E. GERALD STANLEY, M.B., B.S. (Lond.), F.R.C.S. (Eng.), has been appointed Demonstrator of Anatomy at St. Bartholomew's Hospital.

DR. A. S. OWEN has been elected an Assistant Physician to the West London Hospital, Hammer-smith.

PROFESSOR JAMES MARTIN BEATTIE, M.D., M.A., of Sheffield, has been appointed to the chair of Bacteriology in the University of Liverpool.

DR. RICHARD J. REECE, M.A., M.D., D.P.H., Medical Inspector, Local Government Board, has been appointed Assistant Medical Officer to the Board.

DR. A. GOODMAN LEVY, M.D., M.R.C.P., has been appointed Physician to Out-Patients at the City of London Hospital for Diseases of the Chest, Victoria Park.

A BED has been endowed in the Birmingham General Hospital in memory of the late Mr. F. Victor Milward, an Assistant Surgeon to the hospital, who died two years ago.

PROFESSOR PAVLOV, the well-known physiologist, of the University of St. Petersburg, was the recipient last week of the honorary degree of D.Sc. of the University of Cambridge.

MR. W. T. PROUT, C.M.G., M.B., late Principal Medical Officer, Sierra Leone, has been appointed by the Secretary of State for the Colonies Medical Adviser to the Colonial Office in Liverpool.

DR. JAS. GREIG SOUTAR, Medical Superintendent of Barnwood Asylum, Gloucester, has been elected President of the Medico-Psychological Association of Great Britain and Ireland for the year ensuing.

DR. J. S. BOLTON has had the degree of D.Sc. in Physiology of the University of London conferred upon him for a thesis entitled "A Contribution to the Localisation of Cerebral Function based on the Clinico-Pathological Study of Mental Disease."

MR. CHARLES A. BALLANCE, M.V.O., F.R.C.S., has been appointed to represent the Royal College of Surgeons of England on the occasion of the Ninth International Otolological Congress to be held next month in the United States at Harvard University.

DR. JOHN BRIERLEY HUGHES, Secretary of the Stockport, Macclesfield, and East Cheshire Division of the British Medical Association, has been presented with a silver rose bowl on behalf of the members in recognition of his valuable services rendered during the past five years, more especially in connection with the Insurance Act.

SIR RICKMAN J. GODLEE, Bart., was re-elected President of the Royal College of Surgeons of England at a meeting of the Council on Thursday last, when hearty congratulations were accorded him on the bestowal of a baronetcy. At the same meeting, Mr. Clinton Dent and Mr. G. H. Makins, C.B., were elected Vice-Presidents for the ensuing year.

PROFESSOR EDWARD MALINS, M.D., F.R.C.P., has, we learn, resigned the Chair of Midwifery in the University of Birmingham and Mason College, which he has held since 1894, and has presented a sum of £1,000 to the university in recognition of his obligations as a citizen and of the position of the university in furthering the highest interests of intellectual and material progress.

FROM the preessional volume of papers to be read at the Ninth International Otolological Congress at Boston, U.S.A., to be held on August 12th-17th, we see that England will be represented by Messrs. Chas. A. Ballance, A. H. Cheate, Charles Heath, R. Lake, Urban Pritchard, H. Tilley, Walker Wood, and Macleod Yearsley, of London; and Mr. Adair Dighton, of Liverpool.

A CLINICAL LECTURE

ON

THE TREATMENT OF DYSPEPSIA. (a)

By W. H. WILLCOX, M.D., F.R.C.P.

Physician to Out-Patients, St. Mary's Hospital, Paddington.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

(Concluded from page 32.)

CHRONIC DYSPEPSIA.

In these cases the symptoms have usually been persistent for some time, and have generally resisted ordinary treatment. Careful examination will have been made on the lines indicated above, but in many cases some supplementary investigations are necessary before a definite diagnosis can be formed. In such cases an examination of the gastric contents after a test meal should be made.

Early in the morning a pint of very weak tea, containing a little milk and sugar if desired, should be taken by the patient, and with it a piece of buttered toast. After an hour the stomach should be emptied as completely as possible by the soft tube, no water being added. The quantity withdrawn should be measured, and afterwards analysed.

Inflation of the stomach may be effected by giving to the patient soda water to drink, or by the taking of the two halves of a Seidlitz powder separately. This enables the size and position of the stomach to be made out. The size and motor power of the stomach may be determined by the administration of 1 to 2 oz. of carbonate of bismuth given in milk, and X-ray examination should be made every hour after the administration for several hours. In a few cases the gastroscope has been used, but the passage of this instrument is not devoid of risk, and it will on most patients require an anæsthetic.

Chronic Gastritis.—This gives rise to symptoms of chronic dyspepsia, and no gross organic lesion of the stomach is present. The gastric contents show a diminution in the active hydrochloric acid and ferments. Free hydrochloric acid is usually absent, and the gastric ferments are diminished. In treating cases of this kind, careful attention should be paid to the condition of the mouth and teeth. If the symptoms are severe, rest in bed for about a fortnight is advisable, and during this period gastric lavage can be carried out daily. Citrated milk or peptonised milk may be given, 5 oz., every two hours for the first three days. Then junket, lightly boiled, or poached eggs, clear soups, or jellies may be given in addition. When the patient gets up, his diet should be carefully regulated, and only plain, easily digestible food allowed at first, such as fish, boiled chicken, tripe, sweet-breads, toast, rusks, thin milk pudding, etc.

Alcohol should be avoided, and smoking must be prohibited. As regards medical treatment, a mixture such as

Liq. strych., 3 m.
Acid hydrochlor. dil., 14 m.
Tinct. aurantii, ½ dr.
Glyc. pepsin, 1 dr.
Spt. chlorof., 10 m.
Aq., ad. 1 oz.
t.d.s., p.c.

may be given.

Where there is much gastric irritation, the bismuth mixture prescribed above for acute gastritis may be given, and to it, if necessary, may be added glycerine of carbolic acid, 10 m. General hygienic treatment, such as change, congenial exercise, etc., are of great value.

Hyperacidity.—In some cases, symptoms of chronic dyspepsia are associated with an excess of hydrochloric acid and ferments in the gastric contents. While hyperacidity may be a symptom of gastric and duodenal ulcer, it must be remembered that not infrequently it occurs in the absence of any gross organic lesion of the stomach. Rest, either in bed or on a couch, is advisable. The diet should be easily digestible, and citrated milk, or milk containing 1 dr. of bicarbonate of soda to the pint, should be freely given.

A mixture,

Bismuth carb., 10 gr.
Magnes. carb., 10 gr.
Sod. bicarb., 40 gr.
Aq. chlorof., add 1 oz.

should be given one hour after meals.

In some cases the taking of olive oil, a tablespoonful before meals, is of value. The patient should avoid spiced foods, condiments of all kinds, also soups and meat extracts.

Chronic Atonic Dilatation of the Stomach.—In this condition the gastric contents show diminution in active hydrochloric acid and in ferments. Otherwise, there is no marked change. Sometimes organic acids are present in small amounts. This condition is best treated by rest in bed for a few days; the stomach may be thoroughly washed out and emptied at the commencement, and then the patient fed with citrated milk to which beaten-up eggs are added. Horlick's Malted Milk, mixed with water, may be given alternately with the citrated milk. An ounce of liquid may be given every hour for the first 24 hours, and the quantity of liquid only gradually increased. When the stomach has contracted down, light, easily digestible solids may be given; but big meals must always be avoided. It is well to avoid taking liquids with the meals; these may be taken either an hour before meals or between meals.

Abdominal massage is of value, and a nerve tonic such as

Liq. strychnini, 4 m.
Tinct. card. co., ½ dr.
Acid hydrochlor. dil., 10 m.
Aq. chlorof., ad. 1 oz.
t.d.s., p.c.

may be given.

Change and attention to the diet and general health are essential if the recurrence of the symptoms is to be avoided.

Dilatation of the Stomach due to Pyloric Obstruction.—Usually in this condition the presence of mechanical obstruction is shown by the presence of peristalsis.

The nature of the mechanical obstruction, whether due to ulcer, or growth of the pylorus, or gastric displacement, is indicated by the analysis

(a) Lecture delivered at the Medical Graduates' College and Polyclinic, June 3rd, 1912.

of the gastric contents. In this condition medicinal treatment on the lines of atonic dilatation of the stomach may be tried; but massage must be avoided, since frequently an organic lesion of the stomach is present. It will commonly be found that though the patient improves at first under treatment, yet when he gets on to a diet of solid food he speedily relapses. In such cases surgical treatment should be advised, since gastro-enterostomy is strongly indicated.

Congenital Hypotrophic Pyloric Stenosis.—The symptoms of this condition commence usually about the third week of life; they are characterised by the forcible ejection of the stomach contents, almost immediately after taking food, and by the presence of peristalsis and the palpable tumour of the pylorus. Gastric lavage should be done twice daily, and the child fed with albumen water and lactose, or citrated milk, or whey to which somatose may be added. If the loss of weight continues under the treatment, the question of surgical interference must be considered.

Pyloric Spasm in Children.—This gives rise to vomiting in early life, and often peristalsis is visible. No pyloric tumour can be felt, because there is no hypertrophy of the pylorus. Treatment on the above lines is usually followed by marked improvement.

Gastroptosis.—In this condition the gastric contents are usually normal, or may show a slight diminution in the active hydrochloric acid and gastric ferments. The gastroptosis is commonly part of a general enteroptosis. Careful regulation of the diet is necessary, so as to avoid dilatation of the stomach. Nourishing liquid food—*e.g.*, citrated milk, milk puddings, eggs and milk, Benger's Food, etc.—should form the basis of the dietary, and be given every two or three hours. Abdominal massage and faradic electricity will stimulate the abdominal muscles and increase their support. A special abdominal belt should be worn which will give support from below. If these remedies fail, surgical treatment should be resorted to. Eve's operation of suturing the lesser curvature of the stomach to the free border of the liver has given good results. In some cases, gastro-enterostomy may be necessary.

Gastric and Duodenal Ulcer.—The gastric con- may be found. The treatment of this condition should commence with absolute rest in bed. Local tents usually show an excess of hydrochloric acid and gastric ferments; occasionally a trace of blood applications in the epigastrium of poultices, anti-phlogistine, ice, etc., may be used if the pain is severe. Where there has been frequent vomiting or hæmatemesis, it is advisable to withhold food by the mouth for four or five days, and to give rectal feeding every six hours; for example, nutrient enemata of

Somatose, $\frac{1}{2}$ oz.
Glucose, 6 dr.
Normal saline, 10 oz
or,
Glucose, 6 dr.
Yolks of two eggs,
Salt, 8 gr.
Peptonised milk, 10 oz.

Probably, normal saline, 15 or 20 oz., given every eight hours, answers equally well. The mouth should be kept clean by an antiseptic mouth wash, and a few teaspoonfuls of hot water may be sipped if thirst is severe. After the period of rectal feeding, the diet advised by Lenhartz may be given. This consists of 8 oz. of milk mixed with one egg for the first 24 hours; then, daily, 4 oz. of milk and

one egg are added until two pints of milk are given. Afterwards a little scraped raw meat can be given, and later boiled rice, pounded fish, or chicken are given, the eggs being reduced. It is an advantage to use citrated milk in the above dietary. In place of the Lenhartz diet, citrated milk or peptonised milk, to which has been added sodium bicarbonate 1 dr. to the pint, may be given; and to this may be added malted milk, Plasmon, or beaten-up eggs.

In cases of chronic ulceration, where the symptoms do not call for such a severe course of treatment as above, the patient should be put on a liquid diet; citrated milk, with eggs beaten up in it, Benger's Food, or custard may be given. About 5 oz. of liquid every two hours should be given, and, if tolerated, then milk puddings and pounded fish may be added.

A mixture of

Bismuth carb., 20 gr.
Magnes. carb., 10 gr.
Sod. bicarb., 40 gr.
Spt. chlorof., 10 m.
Aq. menth., ad. 1 oz.
t.d.s.

should be given.

In cases of gastric or duodenal ulcer, surgical treatment will be indicated:—

(1) In cases where there is definite pyloric obstruction.

(2) Where there have been repeated attacks of hæmatemesis.

(3) Where there is persistent pain of a severe type.

(4) Where the symptoms have been of long duration, so as to prevent the patient following his occupation, or leading a life of comparative comfort.

It is usual to try medical treatment first in the above class of cases; but if speedy and permanent relief is not effected, it is advisable that surgical treatment should be adopted. Gastro-enterostomy usually gives marked relief in such cases. It cannot be too strongly urged that the great majority of cases of gastric and duodenal ulcer get well, and remain well, after proper medical treatment and dietetic care.

Cases in which gastro-enterostomy is advised should be most carefully selected. In suitable cases there is no operation which is attended with more brilliant results, while in unsuitable cases no benefit will accrue, and the patient may very likely be worse.

Carcinoma of the Stomach.—This condition may be indicated by the symptoms, by the presence of a palpable tumour, and by the character of the gastric analysis. This will show absence of free hydrochloric acid; the active hydrochloric acid is almost always below .1 per cent. Organic acids may be high, especially in carcinoma of the pylorus. The ferment activity is reduced. Lactic acid and mucin are commonly present. This character of the gastric contents associated with persistent dyspepsia and a palpable tumour, make the diagnosis almost certain. The diagnosis having been made, the treatment usually resolves itself into palliative treatment where the patient is given light diet, such as peptonised milk, Benger's Food, light soups, jellies, etc. For the pain morphia should be given in doses of 1-10th of a grain every six hours. This may be conveniently given by the mouth.

A mixture of

Acid hydrochlor., 10 m.
Glyc. pepsin, 1 dr.
Tinct. card. co., 1 dr.
Aq. chlorof., 1 oz.
t.d.s., p.c.

may be given.

It is remarkable how little pain occurs in many cases, and how long morphia or opium preparations may be deferred. Often a little phenacetin will relieve the pain in the early stages. The patient should not be allowed to suffer pain, and, if necessary, hypodermic injections of morphia, or of morphia combined with atropin, should be given as often as required.

As regards surgical treatment, unfortunately, when the signs are such that the diagnosis of this disease is certain, usually, complete removal of the growth is impossible. In early cases removal of the growth may be attempted. When the case is at all advanced, in my experience, Laparotomy usually shortens life very considerably, and is attended by no advantage except the diversion of the patient's mind. Exception should be made to cases of pyloric carcinoma causing pyloric obstruction. Here, undoubtedly, gastro-enterostomy may relieve pain and distress, and prolong life.

The Treatment of other abdominal conditions giving rise to dyspepsia should be carried out in an appropriate manner. It is only proposed to refer to *Colitis*, which is almost invariably associated with dyspepsia, and is frequently complicated by gastric ulcer or hyperchlorhydria. These gastric symptoms require treatment on the line already indicated, and in addition the colitis will require active treatment.

Chronic Appendicitis.—This often gives rise to persistent dyspepsia and constipation. As soon as the condition is definitely recognised it may be cured by surgical treatment.

FUNCTIONAL DYSPEPSIA.

This has been left until last for consideration, because it should not be diagnosed until all possible organic causes for the symptoms have been carefully excluded. In this condition very persistent symptoms of dyspepsia are present, most of which are subjective. The gastric analysis usually shows a normal condition of the gastric contents, though in some cases the gastric secretion may be increased or diminished. In mild cases, change, freedom from business worries and anxieties, exercise, and congenial occupation, are beneficial, and a light nutritious diet may be given. In the more severe cases rest in bed is necessary, and a modified rest cure should be carried out. An examination of the gastric contents should be made, and any excessive secretion may be treated by a mixture of bismuth and alkali. A deficiency of secretion may be treated by hydrochloric acid and pepsin mixture. The patient should be given milk foods at regular intervals. Massage, both abdominal and general should be employed, and the application of faradic or galvanic electricity is often useful. In cases where hysteria is marked, a mixture containing ammoniated tincture of valerian with potassium bromide often does good. Many of these cases are associated with mucous colitis, which may require treatment by intestinal lavage, etc.

Cases of functional dyspepsia are extremely common, and are often the most difficult of all to treat.

Sympathetic treatment on the lines indicated above usually does good, but as soon as possible the patient should be encouraged to take up some hobby or occupation, so that his mind is diverted from his internal digestive processes.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by M. Castaigne, M.D., Professor at the Faculty of Medicine of Paris; Physician to the Beaujon Hospital. Subject: "Digestive Uræmia Simulating Cancer of the Pylorus."

ORIGINAL PAPERS.

ARTHRITIS DEFORMANS AND A PURIN-FREE DIET.

By J. S. KELLETT SMITH, F.R.C.S.ENG.

THE polyarticular, painful form of arthritis deformans is surely one of the most cruel diseases to which the human frame is subject. Its worst feature is that it does not kill, but is capable of subjecting its victim to the extremities of pain and deformity without the hope of a speedy relief.

Text-books of a few years ago stated honestly, according to the lights of their day, that "arthritis deformans is an incurable disease." It still remains incurable to the extent that the anatomical destruction is beyond repair; but on the other hand it is now recognised that many cases—in addition to those of gonococcal, pneumococcal, and some other proven infections—are due either to the action of infective organisms or to the absorption of bacterial products, and vigorous treatment, with this fact as the guide, will often give surprisingly good results. Early diagnosis and early discovery of the sources of the mischief are the essentials of success, and any case or observation which will throw light upon the disease is worthy of report.

In many cases a probable origin is revealed upon physical examination, and amongst such may be mentioned carious teeth, pyorrhœa alveolaris, putrescent masses in tonsillar crypts, nasal catarrhs, frontal sinus and antral suppurations, adenoids, middle ear suppuration, ulcerated hæmorrhoids, suppuration along the urinary tract, tubal disease, vaginal and uterine discharges. The prevalence of these latter probably account for the greater frequency of arthritis deformans in women.

But sometimes the source is difficult to discover, and, when this happens, the alimentary canal must always be regarded with suspicion. Bacterial growth in the intestines is capable of becoming enormous: it has been calculated that as much as one-third the mass of dried fæces may consist of bacteria. Some cases of arthritis deformans give evidence of great putrefaction in the intestine, and good results have been reported in such by cutting down the amount of putrescible proteid in the food, or by feeding for a period on soured milk alone.

One other factor demands consideration. The purin bodies in foodstuffs appear to act upon some persons as powerful irritants of the intestinal mucous membrane. Experimentally they have been shown to do so when taken in large quantities, and it is justifiable to assume that people with unstable mucous membranes will re-act in the same way to small doses of purin which the normal person would assimilate with impunity. A mucous membrane which has become catarrhal is no longer efficient as a barrier. Hence the question of this local effect of the purins crops up in this connection as an important one, and it becomes advisable to know the amount of purin contained in the various common articles of diet.

The following analyses are taken from Dr. Hutchison's compiled tables, whilst the purin figures are from Walker Hall's work on the subject:—

	H ₂ O	Proteid	Fat	Carbo- hydrate	Ash	Purin grs. per lb.
Rabbit	66.8	21.4	9.7	—	1.1	6.3
Mutton	65.2	14.5	19.5	—	0.8	6.8
Veal	71.0	17.0	11.0	—	1.0	8.1
Pork	60.9	12.3	26.2	—	0.6	8.5
Beef	76.5	20.0	1.5	—	1.3	8.6
Turkey	60.3	23.4	15.0	—	1.2	8.8
Chicken	70.2	21.0	7.6	—	1.1	9.0
Steak	—	—	—	—	—	14.5
Liver	61.2	23.1	9.0	5.0	1.7	19.3

In the case of turkey and of chicken the analysis is of the dark and light meats taken together, the former being richer in fat and poorer in proteid than the latter.

The comparatively large amount of purin in liver is not unexpected: not only is the liver the seat of great tissue activity, but here also the oxidation of hypoxanthin and xanthin to uric acid takes place. Beef steak contains a larger proportion of muscle tissue to fat, etc., than the ordinary joint, and therefore gives a larger purin figure.

For the remainder it is to be noticed that they are much on the same level; the "heavier" meats (pork and veal) containing a little more than the "lighter" kinds and a little less than poultry.

The purins of muscle tissue (xanthin and hypoxanthin), being soluble in water, are found in large quantity in concentrated meat preparations. The percentage proportion of "extractives" in four largely-advertised beef teas was 24.14, 21.7, 31.79, and 39.60; in one beef jelly, containing much gelatine, 1.01; and in one beef extract, 40.56.

	H ₂ O	Proteid	Fat	Ash	Purin grs. per lb.
Cod... ..	82.6	16.5	0.4	1.2	4.0
Plaice	77.86	16.6	—	—	5.6
Halibut	75.4	18.6	5.2	1.0	7.1
Salmon	64.6	22.0	12.8	1.4	8.2

In this table the "rich" fishes show the highest purin content.

	H ₂ O	Proteid	Fat	Carbo-hydrate	Purin grs. per lb.
Onions	89.1	1.6	0.3	6.3	0.063
Potatoes	73.3	2.2	0.1	18.0	0.14
Asparagus	91.7	1.1	0.2	2.9	1.5
Pea Flour	10.21	27.98	1.97	56.93	2.54
Oatmeal	7.2	14.2	7.3	65.9	3.45
Beans	11.7	23.0	2.3	55.8	4.16
Lentils	11.7	23.2	2.0	58.4	4.16

In plants the products of tissue change, other than gases, are chiefly stored—and so excreted from the active regions—in the bark, husks, leaves, etc. Hence the purin content is low in relation to the proteid.

	H ₂ O	Proteid	Fat	Carbo-hydrate	Purin
Eggs	73.7	14.8	10.5	—	None
Milk	87.10	3.25	4.0	4.5	Negligible
Butter	13.5	Small quantity	82.0	Small quantity	"
Cheese	33.2	29.4	30.7	—	"
Fine Wheat Flour... ..	13.0	9.5	0.8	75.3	None
Rice (husk removed)... ..	12.0	7.2	2.0	76.8	"
*Tapioca	11.5	Practically none	—	87.5	"
Cabbage	89.6	0.9	0.4	5.8	"
Cauliflower	90.7	1.1	0.4	4.7	"
Lettuce	94.1	0.7	0.4	2.6	"
Sugar	—	—	—	—	"

*Macaroni is also purin-free, and fruits and nuts may be regarded as permissible.

This is an important table since it indicates the constituents of a purin-free diet. Milk and its derivatives are practically purin-free, presenting only a minute trace derived from the leucocytes contained in the milk.

From these purin-free foods a surprising number of dishes can be prepared by a skilled cook. The green vegetables and salads provide the necessary "ballast," and are also valuable for their mineral salts, carbohydrates are abundant, and there is no difficulty over fat. The weak point is the fact that the proteid is derived from articles which are apt

to pall, and in many cases to disagree if taken continuously. Eggs, for example, may prove indigestible when eaten frequently, and may give rise to very disagreeable sulphur compounds. The greasy taste of raw milk, which is repulsive to many people, may be mitigated by heating and flavouring with nutmeg or cinnamon, and the freshly-made cream and plain curd cheeses can be tolerated longer than the matured and flavoured kinds.

If difficulty arises in this respect the proteid quotient may be supplemented by commercial preparations, the best of which give a high nitrogenous content, easily digested and absorbed, and quite suitable for prolonged use.

As regards beverages, beers and stout contain an appreciable quantity of purin; wines are free, but have other constituents irritative to the intestinal mucous membrane; spirits are purin free.

Caffeine, theine, or methyltheobromine, is found in coffee-beans ($\frac{1}{2}$ per cent.), in tea (2 to 4 per cent.), in kola-nuts (2.5 per cent.), and in some other vegetable products.

Theobromine, which strongly resembles caffeine in its properties, occurs in cocoa-beans.

The following is quoted in illustration of the application of the purin-free principle of diet to a case of arthritis deformans:—

A. J., æt. 37, formed himself with arthritis deformans of both knees, wrists, and the left index metacarpo-phalangeal joint. Perfectly healthy up to about a year ago when he began to suffer from a feeling of weakness, pain, and swelling in the knees, especially after prolonged exertion. At the present time the disease is well marked in the knees, he is obliged to use a stick and to mount stairs one step at a time.

Family history shows Bright's disease on the father's side. The one important thing in his previous personal history is the evidence of instability of his mucous membranes. He has been obliged to give up his moderate smoking owing to throat trouble, and has restricted his diet to simple foods, having found that rich dishes (stews, made entrées, pork, salmon, etc.), caused abdominal pain followed by mucous diarrhœa. He has continued, however, to take the usual plain meats. General habit rather constipated.

Strict examination (nose, throat, ears, urine, etc.), failed to reveal anything abnormal. It was therefore concluded that the source of infection lay in the intestinal mucous membrane.

Treatment:—Local.—Massage and movements of the knee joints, together with Ionic Medication with sodæ sal. for twelve applications.

General.—(1) *Strict purin-free diet.* (2) beta-naphthol (gr. 6) three times a day. (3) A small dose of MgSO₄, in a tumblerful of hot water, first thing each morning.

The improvement in three weeks was so marked that the knees were practically free from pain, swelling greatly diminished, and he was able to walk up and down stairs in the usual manner. The wrists were proportionately relieved.

Thence onwards the conditions were gradually somewhat relaxed—the beta-naphthol was given up, the MgSO₄ taken only when required, and he was allowed potatoes, cod, whiting, sole, fresh haddock, the fat part of bacon, and boiled mutton. *But these articles of low purin content were taken always in very limited quantity, and rather as a relish than as the main substance of a meal.* Gravies and meat soups were, of course, prohibited.

In six months he reported that his general health was excellent, that the particular food was no longer a trial, and that he doubted whether he would revert—even with permission—to heavy meats as

the mainstay of his diet. As regards the affected joints, he had marked continuous progress to the good, and he was now following his usual busy life without restraint, and was able to cycle and to dance freely.

THE CLINICAL SIGNIFICANCE OF ACIDOSIS IN PREGNANCY.

By WALTER C. SWAYNE, M.D.

THE occurrence of acidosis has for some time been recognised as a phenomenon connected with the special toxæmias of pregnancy, and in this paper an effort is made to show how its presence can be ascertained by tests which are not too complicated to be carried out in clinical practice, and how the diagnosis and treatment of the case may be influenced by its occurrence.

It should be explained before going any further that the methods described are not intended to produce absolutely accurate results from the point of view of the physiological chemist, nor is there any attempt made to deal with the affections mentioned from the point of view of the pathologist, or to advance any theories as to the ætiology of the disturbance of metabolism which leads to the production of acidosis, but simply to record the results of the investigation of a series of cases, and the suggestions as to the treatment of the causative condition which seem to be the result of the investigation.

Acidosis is used as a term signifying an alteration in the ammonia-urea nitrogen ratio in the urine, accompanied by the presence of acetone and diacetic and beta-oxybutyric acids.

The quantitative estimations used are not absolutely accurate, but are sufficiently so for clinical purposes, and the amount of inaccuracy (which is not great) when it occurs in the same case under such conditions—for example, as before and after delivery—does not affect the comparisons to any material extent. For the methods of quantitative estimation used I am indebted to Dr. Herapath and Dr. R. E. Thomas, late of the Bristol Royal Infirmary; and the actual estimations have been worked out by Dr. R. S. S. Statham, Resident Obstetric Officer to the Bristol Royal Infirmary, and confirmed, in many cases, by Professor Kent and Dr. Bywaters, of the Department of Physiology of the University of Bristol.

Leith Murray (1), in his paper on the "Toxæmias of Pregnancy," alludes to the occurrence of acidosis in cases of vomiting of pregnancy and in eclampsia, and states that these two forms of pregnancy toxæmia, while not necessarily due to the same toxin, are probably due to the same type of toxin. It is not, however, in this paper proposed to do more than call attention to Leith Murray's investigations, since these are more particularly concerned with the pathological conditions found, but rather to point out the clinical importance of the occurrence of acidosis.

Acidosis occurs in diabetes, in which its occurrence was first noted (A. R. Short), (2) and in the following other conditions: Starvation, periodic vomiting of children, delayed chloroform poisoning, severe vomiting of pregnancy, and the pregnancy toxæmia which terminates in eclampsia. Two of the conditions named are, as Leith Murray has shown, the result of a toxæmia especially occurring during pregnancy. To refer to some of these conditions in detail:—

Diabetes is accompanied by marked acidosis, and pregnancy not infrequently occurs in a woman suffering from this disease. Just as muscular exertion may precipitate an attack of diabetic coma due to the increase of the acidosis, so may the muscular strain of labour, and consequently labour in a diabetic woman should be looked upon as attended by a grave risk, and every possible precaution taken to render it as free from exertion as possible.

The administration of chloroform as an anæsthetic will produce an acidosis in a healthy subject (A. R. Short (3); Muskens and Frew) (4), and the sequence of events classed under the name of delayed chloroform poisoning is largely due to the acidosis. Obviously, therefore, the use of chloroform as an anæsthetic in

cases of parturition in which the patient is known to be suffering from an acidosis is to be avoided, and a case is quoted below which gives an instance of its danger.

The occurrence of albuminuria in a pregnant woman is one of the signs of the presence of a pregnancy toxæmia, but neither the mere detection of the presence of albuminuria, nor the quantitative estimation of the albumen present is sufficient. If albumen is found, the daily output of urea should be estimated, as this is an important indication of the manner in which metabolism is being carried on, and in addition the presence or absence of an acidosis should be ascertained. A well-marked acidosis occurs in cases suffering from the vomiting of pregnancy (Whitridge Williams (5) Leith Murray) (6) in nearly all cases in which the vomiting is severe, and occasionally in cases in which the vomiting is only slight. Every such case of vomiting, whether severe or not, calls for the application of tests to ascertain the presence or absence of an acidosis. In one case (No. 4), in which the vomiting could not be called severe, a marked acidosis was present. In one case a patient was reported to be suffering from severe vomiting of pregnancy before her admission to hospital, and on account of this report the usual investigations for acidosis were carried out and its presence ascertained. Observation after admission showed that the vomiting was only slight, not more than once or twice daily. She did, however, suffer from profuse ptalism. Treatment directed to the reduction of the acidosis not only did so, but was accompanied by the disappearance of the ptalism. This rather suggests that ptalism may be one of the expressions of a pregnancy toxæmia, and the case is mentioned in the hope that other observers may be able to produce evidence either in support or contradiction of this suggestion. It should be stated that this patient, in addition, presented a well-marked papillitis on examination of the fundus oculi. Several cases have been investigated to ascertain whether acidosis occurs in the case of pregnant women showing no pathological symptoms, but with results entirely negative. Several other cases have also been investigated to ascertain whether acidosis occurred in cases of albuminuria due to a primary nephritis in the non-pregnant. The results here were also negative. In one case (No. 6) the patient was known to have suffered from a chronic nephritis, and an acidosis was found. There is no reason why a pregnancy toxæmia should not occur in addition to a pre-existing chronic nephritis. In one case of post-partum eclampsia no diacetic acid was found, although there was a large disturbance of the urea-ammonia nitrogen ratio.

It seems that from the facts mentioned above, it may be inferred that acidosis occurring in a pregnant woman suffering from albuminuria indicates a pregnancy toxæmia, although to prove this conclusively the investigation of cases of albuminuria in pregnancy without acidosis is necessary. So far, this evidence is wanting, since all the cases of albuminuria investigated showed an acidosis. All, however, suffered from some well-marked symptoms which led them to seek advice. One patient who was admitted suffering from albuminuria with acidosis, responded to treatment to such an extent as to lead to the disappearance of the ammonia nitrogen, diacetic acid, and a rise of the daily urea output to near normal, but she was re-admitted to hospital some weeks later with a recurrence of the previous conditions, and in spite of treatment, actually did become eclamptic. But in the majority of cases treated, eclampsia did not supervene, although the acidosis persisted until after delivery. In all of the cases the acidosis disappeared within a comparatively few hours after delivery, so that pregnancy is undoubtedly the determining factor in producing the toxæmia, and its cessation leads also to the cessation of the toxic symptoms. In Leith Murray's paper it is suggested that the acidosis, in cases of pernicious vomiting, is due to the starvation produced by vomiting. (Starvation acidosis has been already referred to.) In some of the cases of albuminuria investigated, however, and in one case of the vomiting of pregnancy, the patients

were receiving no food by the mouth whatever, but injections of glucose and saline solution per rectum only. This treatment did not, however, materially affect the acidosis. In spite of this treatment being continued after delivery, and no food given by the mouth, the acidosis disappeared almost entirely, so that it would appear that the occurrence of acidosis is not wholly due to starvation in these cases. In one case a primigravida suffering from vomiting, which was not of a severity to prevent her taking food, and, as a matter of fact, only came on just before meals, was found to have diacetic acid in the urine and an increase of ammonia nitrogen, with diminished urea output. The acidosis, however, in this case was not severe, and the percentage (6 per cent.) of ammonia nitrogen not high. It seems fair to infer that in this case the small amount of vomiting present did not lead to starvation, and that the occurrence of acidosis should be attributed to a slight pregnancy toxæmia.

DIAGNOSIS.

The extent of the acidosis in a case of vomiting

should give some indication as to whether the cause of the vomiting is a toxæmia of pregnancy or due to come accidental complication causing vomiting in a pregnant woman. In albuminuria, acidosis points to a pregnancy toxæmia rather than a primary nephritis.

USE OF CHLOROFORM.

The following instance shows the danger of administering chloroform to a patient with acidosis. A patient suffered from vomiting of such severity as to necessitate the termination of pregnancy. This was done under chloroform, the presence or absence of acidosis not having been ascertained. Within 48 hours the patient became comatose and suppression of urine occurred. The coma was recovered from after an intravenous injection of sodium bicarbonate, but the patient died a week later from uræmia. Albuminuria had not been proved to be present at any period before the termination of pregnancy, and the fact that diacetic acid was present in the urine was not ascertained in sufficient time to prevent the administration of chloroform as the anæsthetic. In this

case the cause of coma seemed almost certainly to be the rise of the acidosis due to chloroform, which, unfortunately, was the anæsthetic used in emptying the uterus. In one case in the table (No. 14) chloroform was given inadvertently in the absence of the Resident Obstetric Officer. The acidosis rose markedly after this.

At the Bristol Royal Infirmary the disuse of chloroform as an anæsthetic has been followed by a marked improvement in the mortality rate of cases of eclampsia. It seems highly probable that many of the deaths which occurred in previous series when chloroform was used as the anæsthetic were due to coma as the result of the acidosis produced by chloroform.

Chloroform is no longer used as an anæsthetic in any case of eclampsia or in any case of pregnancy where acidosis is present. Cases of pregnancy toxæmia are treated by the administration of glucose and saline by the rectum. If looked upon as pre-eclamptic, the diet is limited absolutely to milk, and if the general symptoms present are at all severe, by restriction to water only. The cases of vomiting are also treated in the same way, food by the mouth being excluded, but in either case a marked rise in the acidosis is looked upon as an indication for more drastic treatment, such as emptying the uterus.

PROGNOSIS.

A marked rise of the ammonia nitrogen should be considered as an indication for the termination of the pregnancy in cases of severe vomiting and also in cases of albuminuria, provided that it cannot be accounted for in a way to be presently mentioned.

TESTS AND METHODS OF ESTIMATION.

The first step is to test the urine for diacetic acid. This is a simple matter, merely needing the addition to three cubic centimetres of urine of a few drops of liq. ferri perchlor., when a deep red colour, which disappears on heating, is positive evidence of its presence. The tests for acetone and beta-oxybutyric acid are not essential, since the presence of these substances is almost a necessary corollary of the presence of diacetic acid. If diacetic acid is found the urea-ammonia nitrogen ratio should be worked out.

The following are the methods of estimation:—The total urea excretion is found by the hypobromite method. The total excretion in grains per diem multiplied by 0.0303 gives the number of grams of nitrogen passed as urea. To find the nitrogen passed as ammonia 25 c.c. of urine are shaken up with about 2 ozs. of solution of potassium oxalate (strength 15 gr. to the ounce) to clear the urine and precipitate calcium salts. The solution is neutralised; 10 c.c. of 40 per cent. formalin are neutralised. These two are shaken together. The formalin combines with the ammonia bases of the diacetic and beta-oxybutyric acid salts, forming urotropin, and the acids are set free in solution. The solution is then titrated against a decinormal solution of caustic soda; then the number of cubic centimetres of caustic soda multiplied by the number of ounces of urine passed in 24 hours, multiplied by 0.0016 gives amount of ammonia nitrogen in grammes, and from this the percentage of ammonia nitrogen in the urea nitrogen and the ammonia nitrogen combined can be easily worked out.

SOURCES OF ERROR.

One patient developed an attack of cystitis with ammoniacal urine and enormous apparent increase of ammonia nitrogen. It is unnecessary to do more than indicate this complication as a possible source of error. Also if the analysis is made from a 24 hours' specimen, a certain amount of decomposition of the urea may have occurred in the course of 24 hours. In a comparison between the pre- and post-partum condition this error would be common to both.

The conclusions to be drawn may be briefly recited as follows:—

- (1) Administration of chloroform to a patient with acidosis should be avoided, and chloroform should not be used for patients suffering from eclampsia.
- (2) An increasing acidosis should be looked upon as

an additional indication for terminating pregnancy in cases either of albuminuria or severe vomiting.

(3) To the ordinary treatment of these conditions should be added measures directed to the correction of the acidosis.

With reference to the table of cases, many of the investigations are incomplete owing to the difficulty in obtaining an uncontaminated 24 hours' specimen in every case. In each case in which the uterus was emptied, either naturally or artificially, that occurrence is indicated by *Partus*. The occurrence of convulsions is also indicated by *Fits*.

SUBMUCOUS RESECTION OF THE NASAL SEPTUM: AN ANALYSIS OF 130 CASES.

By DAN MCKENZIE, M.D., F.R.C.S.E.,
Surgeon, Central London Throat and Ear Hospital.

CONCERNING the general question of the utility and safety of the submucous resection of a deviated nasal septum in properly selected cases there can be no dispute. This paper deals only with certain details in regard to the operation and its results.

Indications for Operation.—The operation is, of course, most frequently performed for the relief of nasal obstruction arising from deflections, outgrowths, or spurs of the septum. Ninety-one of my cases were operated on for this reason.

In addition to nasal incompetence sufficiently disturbing to lead the patient to seek relief from this disability, the operation may be necessary in cases where the secondary effects of the nasal obstruction are more striking than their initial cause. Seventeen of my cases fall into this group. Seven of these were cases of chronic laryngeal catarrh, more or less severe, all of which were materially benefited by the operation. In one case suffering from laryngeal tuberculosis the restoration of nasal patency by the operation was followed by a surprisingly good effect upon the laryngeal disease. Four were cases of chronic catarrhal deafness, two of which were improved by the operation, while two received no benefit. Three patients were operated on for the removal of the annoyance of "dropping mucus" in the back of the throat; one was cured, and the other remained as before. One case of anosmia was operated on with a negative result.

We are generally warned to abstain from the septal operation in cases of atrophic rhinitis, and I admit that this teaching is, as a rule, sound. But when the atrophic disease is found affecting only one side—the widely open side—of a nose with a deflected septum it may be worth while to depart from the rule. At all events, in the solitary case of this kind in which I performed the operation the atrophic disease rapidly got well.

There are other indications for the operation besides obstruction, less common, no doubt, but, when they are present, not any less cogent.

In eight of my cases a deviated septum was straightened in order to permit free access to the antrum, the ethmoidal, or the sphenoidal region, so that a polypus-bearing area might be efficiently curetted, or drainage provided for the discharging cavities. The frequency with which sinus suppuration and polypus formation are found on the stenosed side of an asymmetrical nose suggests a causal connection between the deflection and the disease, which, of itself, is, perhaps, sufficient justification for the operation. In one of these cases did the presence of sinus suppuration induce septic infection of the septal

wound area. A rare indication for the operation existed in one case where a septal deflection hindered the surgical removal of a congenital occlusion of a posterior naris. It may be remembered in this connection that recourse to septal resection as the first step in a more extended surgical procedure has recently been had by Hirsch, of Vienna, in selecting the septum as the route of approach to the region of the pituitary body inside the cranium.

Turning to the removal of possible causes of reflex irritation by septal resection, I find eleven cases, six of which were cases of asthma. Of these one obtained complete relief from his attacks, a relief which still continues, two years after his operation; one remained free of asthma for eight months and then relapsed, though the attacks were less severe; two reported themselves "improved" by the operation; and in two it has done no good whatever.

Three cases were operated on for headache; two were cured and one remained unaffected.

Two cases were operated on for paroxysmal rhinorrhœa, and both were greatly improved.

It is, perhaps, necessary to say that in all these cases of presumably reflex irritation the condition of the septum was sufficiently abnormal to suggest that circumstance as a likely starting-point of the reflex irritation.

In two cases the septum was resected for quite extraordinary reasons. In one, a boy, aged ten, there was extreme deviation coupled with extensive adhesions between the septum and the inferior turbinals on both sides. The nose showed a peculiar stunting in its growth, affecting chiefly the cartilaginous portion of the external nose. In the belief that this mal-development was due to the bridling action of the adhesions upon the normal growth of the septal cartilage, I performed submucous resection and divided the adhesions. So far, however, the operation has not been followed by any improvement in the shape of the nose.

In the second case, the patient, a young lady, was annoyed by a persistent whistling sound proceeding from the nose. It originated in a narrow chink between a deviated septum and an enlarged middle turbinal, and was, of course, cured by the operation.

There is one variety of nasal obstruction for which submucous resection avails little or nothing, namely, in the pinched or collaterally compressed nose associated with the "Gothic" palate. In one case of this kind treated by submucous resection no benefit whatever resulted, and even complete resection of the septum with the intentional formation of a large perforation, to which I resorted to render the interior of the nose more roomy, failed to provide the patient with a useful nose.

THE OPERATION.

All the cases were operated on according to the principles of Killian.

Anæsthesia.—Eighty-two cases were operated on under general and forty-eight under local anæsthesia. With increasing practice in the *technique* I find I am using local anæsthesia more and more and general anæsthesia less. At the same time the inevitable discomforts attendant upon any operation under local anæsthesia always renders it unsuitable for sensitive people. In ordinary cases, however, a hypodermic injection of morphine (gr. $\frac{1}{4}$) or scopolamine and morphine (gr. $\frac{1}{100}$ and gr. $\frac{1}{4}$) will soothe these discomforts and facilitate matters both for the patient and for the surgeon.

Whether the patient is conscious or unconscious the recumbent position is the most convenient. But the head and shoulders should be raised, otherwise there is a tendency in operating to deviate upwards away from the base of the septum. By so doing I twice inadvertently left behind large basal spurs.

In operating under cocaine with the patient sitting up, syncope interrupted progress five or six times; twice the patient became sick and vomited, and on one occasion the cocaine poisoning was so severe that the operation had to be abandoned. Vomiting during the operation is likely to lead to infection of the wound,

and its occurrence, whether with local or general anæsthesia, is therefore objectionable.

These risks can be minimised by operating under local anæsthesia upon a recumbent patient. It is advisable, however, to insert the cocaine-soaked tampons before the patient lies down, so as to lessen the likelihood of some of the solution passing into the pharynx and being swallowed.

I have recently been using Freer's plan of applying cocaine crystals to the area of operation, and am rather pleased with it.

Asepsis.—Sepsis after submucous resection of the septum may manifest itself in several different ways. The commonest is follicular tonsillitis, a sequela which is due to carelessness in technique, and is avoidable.

Acute rhinitis is another common septic accident. One of my cases developed membranous rhinitis from infection with the pneumococcus, and was left with a perforation in the septum, due, I think, to the action of the organism. In another case of post-operative rhinitis the *Bacillus capsulatus mucosus* was, according to Dr. Wyatt Wingrave, the responsible agent—after the operator. In two of my cases, nasal sepsis following the operation apparently led to ethmoidal suppuration. In none, however, did the septic infection give rise to any anxiety.

In order to avoid these tedious complications, the lips, chin, cheeks, the outside of the nose, and, above all, the vestibule, should be surgically cleansed before operation. The interior of the nose, however, should not be treated in this way, even when there is already sinus suppuration present. The field of operation should be isolated by covering mouth, lips, and nose with sterilised gauze.

Some Points in Operative Technique.—Every operator evolves his own minutiae, and I have no intention of describing in detail all my own particular devices. I may be permitted, however, to mention one or two points.

In the raising of the muco-perichondrium, a crucial point is reached when we pass from the cartilaginous to the bony section of the anterior septum, especially when there is a sharp-pointed spur or a deep gutter or recess to be negotiated. The reason is that the sub-perichondrial space is not continuous with the sub-periosteal space. The bone is completely enclosed in periosteum, and the penetration of the periosteal sheath from the sub-perichondrial space, especially when it is thick and tough, presents some little difficulty. The quickest and easiest method is to lay aside the elevator, and to cut through the fibrous barrier with a sharp knife. If the edge of the knife is turned towards the bone, button-holing of the flap will be avoided. The judicious use of the sharp knife at any stage is, indeed, one of the secrets of success in the operation.

There is no need to dwell upon the host of elevators, forceps, and gouges that have been devised for the operation, every specialist worthy of the name having invented his own. But I should like to draw attention to two points. First, when forceps are used to remove the vomerine plate at the back of the septum, it is advisable, I think, to cut clean through the bone without any twisting, rocking, or wrenching. Otherwise, we may produce a fissuring fracture, the range of the extensions of which we can neither foretell nor determine. Secondly, only so much of the cartilage and bone should be removed as is necessary to relieve obstruction and pressure, or to provide space for subsequent manipulations. I am quite sure that an artistically symmetrical and mathematically straight septum is no advantage. Rather the reverse, indeed, for by rendering the nasal passages too roomy it may substitute one evil for another, and transfer the patient from the troubles of nasal obstruction with its hypertrophies, to those of nasal spaciousness with its crusts and atrophies. In this respect, indeed, each case must be treated on its own merits, the operator forming a picture in his own mind as to how much or how little of the septal cartilage and bone ought to be removed.

Perforations and Button-holes.—In the submucous resection of the nasal septum, button-holing is a misfortune and perforation a disaster. It is true that many a man is going about the country to-day who is quite unaware of the perforation in the septum, and there is therefore a tendency to look upon perforations as of no consequence. All the same, no rhinologist can pretend to himself that he is pleased when a perforation results from this operation, expressly devised as it is to avoid such an occurrence. Moreover, it is questionable whether perforations are invariably the innocent and harmless conditions we hope them to be. At the same time, if an obstruction cannot be removed without making a perforation, then I suppose it is better to make the perforation. With experience, however, it is astonishing how even the apparently inevitable can be avoided. In these 130 cases I have sixteen perforations, most of them quite small, and most of them in my early cases.

Perforations are not always produced at the operation. There can be no doubt that extensive bruising, brusque handling of the flaps, or prolonged pressure from a too lengthy operation, especially when combined with sepsis, may set up sloughing and a perforation which surprises the operator when his patient presents himself for inspection a week or two after the operation. For this reason, therefore, other things being equal, the most successful operator is he who combines celerity with gentleness and ease of manipulation.

Button-holes.—We make button-holes oftener than our onlookers imagine. They do not necessarily lead to perforation, and thus they are generally disregarded. But they ought not to be; for the edges of a button-hole may gape and flap; granulations may sprout up around it; and in the reactionary swelling after the operation adhesions may form which will give rise to trouble at a later date. Apart from synechia, button-holes mean the ultimate presence of an area of non-ciliated scar-tissue and the likelihood of crust-formation.

Difficulties.—Apart from everyday difficulties like sharp spurs, deep gutters, traumatic deviations with adhesions, and so forth, one one occasion I encountered a septal cartilage with a considerable fenestra. Fortunately, the condition was recognised in time, and a perforation was avoided.

In those cases in which the so-called "columnar cartilage" is displaced into one vestibule, the main septal deviation lying behind, the removal of the whole cartilage—vestibular and nasal portions—is open to the risk of withdrawing most of the support from the point of the nose. A device to which my attention was drawn by Dr. Dundas Grant enables us to avoid this danger. It consists in making an incision over the dislocated cartilage, and removing it, and then making another incision further back than the first in order to resect the more posterior part of the septum. Between the two incisions a shore or prop of cartilage is left which supports the tip and columella of the nose, and, as it occupies the middle line, it is non-obstructive.

Another common difficulty is met with where the deviation is so extreme that the bend in the cartilage extends up to the bridge of the nose. In such cases our operation voyages between Scylla and Charybdis. If we remove the cartilage close up under the bridge we risk external deformity. If we leave it, the flap depending from it occupies much the same position as the septum itself did before the operation.

Troublesome Sequela.—Two results of operating, even when the operation itself has been quite successful, may give rise to subsequent trouble. One is turbinal engorgement, which, by inducing nasal obstruction, may render the patient doubtful of receiving the benefits he has been promised. Generally speaking, simple treatment or the use of the cautery will bring about cure of this condition. But there are several cases in my list in which the trouble persisted for a year or eighteen months. I assume that this disturbance is due to local shock, if not infection, upsetting the nasal vaso-motor system. The other objectionable after-result is an obstinate tendency to the formation of small fine crusts—a dry rhinitis—which has affected some six or

eight of my cases; all of them, however, finally recovered. This sequel may be ascribed to the operation depressing the vitality of the ciliated cells of the septal mucous membrane. The lesson to be learned from these occurrences is, I take it, that the operation should be speedily performed, and with as little traumatism as possible. Plugging after the operation, for example—an unfortunate necessity—should be done with gauze dipped in sterile vaseline so as to minimise the risk of damage to the superficial cells of the mucosa.

In two cases it was found that the mould of muco-periosteum covering a basal spur still retained its original bulging position, in spite of the fact that the bone it had enclosed had been completely cleared away by means of a chisel at the operation. That is to say, that the sheath of soft tissues, being stiff and rather resistant, did not spontaneously flatten down after the bone inside it had been removed. The true state of matters was, however, disclosed on probing the prominence, and the remedy was simple.

Age.—My youngest patient was ten years old, the oldest sixty-one. But the majority were males between eighteen and twenty-five years of age. It is not yet settled whether operation may be performed in early childhood without interfering with the subsequent growth of the nose. But Mr. Westmacott and others who have paid particular attention to the point have not reported any postponed deformity following an operation performed in childhood.

Results.—The greater the nasal obstruction the better is the patient pleased with the operation. We may note here that after the straightening of a deflected septum and the consequent opening-up of the nasal chambers to the air currents the voice becomes richer and more resonant—a grateful result, particularly in patients who are actors, singers or public speakers.

In conclusion, let me remind you that the operation necessarily impairs the strength of the skeleton of the nose, and that a blow, even a slight blow, upon it may flatten the organ beyond recognition and beyond remedy. For this reason, boxing, football, wrestling, etc., should be avoided by people who have had the septal resection performed unless they wear some kind of nose-guard. That there have been cases in which the operation has been followed by spontaneous flattening of the end of the nose is perfectly true, and it is possible to imagine circumstances in which such an event would be inevitable, but these circumstances must be rare.

In this paper I have necessarily dwelt chiefly upon certain unpleasant and disturbing events which occasionally attend upon the operation, but it would be wrong to let the impression get abroad that such mishaps are common. It is not so. In suitable cases there is, perhaps, no operation in surgery where the patient risks so little to gain so much.

OPERATING THEATRES.

TEMPERANCE HOSPITAL.

APPENDICECTOMY FOR APPENDICULAR GASTRALGIA.—MR. PATERSON operated on a woman who had been admitted into the hospital giving a history of having suffered from indigestion and a heavy feeling after food accompanied by flatulence for the last five years. About four years previous to admission she became ill, had pain coming on immediately after food and lasting until she vomited, which occurrence usually took place about 15 minutes after a meal. After vomiting the pain was better until the next meal. This attack lasted four months, and the patient gradually got better and was well for twelve months with the exception of indigestion, with which she was constantly troubled. The woman had a second similar attack, then was well for two years. The patient had a third attack one year before admission to the Temperance Hospital, when she went into another hospital for two months and was treated with gastric lavage. During the attacks the pain was often so severe that it doubled her up.

The patient remained on milk diet, and later was

only able to keep down soda and milk, and even that gave her pain. During the fourth attack she was admitted under the care of Mr. Paterson's colleague, Dr. Soltan Fenwick. On admission the patient was suffering from constant vomiting, which improved with gastric lavage. She left hospital, and was well for two weeks. She was then re-admitted. At this time the vomiting was so severe that patient had to be fed per rectum and had gastric lavage. The vomiting usually occurred twice daily.

She referred the pain to the epigastrium, and said it went through to the left shoulder. After medical treatment the pain was less severe, but it still came on soon after taking food. The case was diagnosed as one of appendicular gastralgia. An analysis of the stomach contents gave the following result:—Total chlorides, 0.306; free HCl, 0.003; protein chlorides, 0.222; mineral chlorides, 0.080; total acidity, 52.

On opening the abdomen, the stomach was found to be large. There was nothing abnormal in stomach, duodenum or gall-bladder. The appendix was discovered to be acutely kinked near its extremity by its mesentery. Appendicectomy was performed. The jejunum was kinked by a long ligament of Treitz, which was divided. The appendix measured $5\frac{1}{2}$ inches in length, and contained three oval concretions, each of which measured three-eighths of an inch in length. The mucosa at the site of the concretions was ulcerated.

Mr. Paterson pointed out that there were three points of interest in the history of the case—(1) the chronicity of the symptoms; (2) the periodicity of the symptoms; (3) the severity of the vomiting. In some respects the symptoms were suggestive of gastric ulcer. He regarded gastric ulcer as an uncommon disease. The supposed symptoms were often present, but the lesion was elsewhere than in the stomach, usually in the appendix. In this case the character of the pain and the gastric analysis suggested appendicular disease. The character and severity of the vomiting, however, was quite unlike that usually associated either with gastric ulcer or with appendicular disease. Except when there is pyloric stenosis, vomiting is not a marked feature of gastric ulcer. In this case there was no evidence clinically of pyloric stenosis, and at the operation the pylorus was found to be perfectly patent and normal. In appendicular gastralgia vomiting often occurs, but not in such large amounts as in this instance. The operation had revealed the cause of these severe attacks of vomiting. He had no doubt that they were directly due to the long ligament of Treitz which caused kinking of the jejunum, and so led to obstruction to the normal flow of the intestinal contents.

It was remarkable with what fidelity the supposed symptoms of gastric or duodenal ulcer might be mimicked by lesions in other parts of the abdomen. Chronic appendicular disease, gall-bladder disease, kinks of the ileum, and stricture obstruction of the transverse colon gave rise to symptoms which might be readily mistaken for those of a gastric or duodenal lesion. As a rule a careful examination as to the detailed history of the case would suffice to distinguish these conditions.

The patient made an uninterrupted recovery.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD JULY 4TH, 1912.

The President, DR. AMAND ROUTH, in the Chair.

DR. W. BLAIR BELL, of Liverpool, read a short communication on

THE PATHOLOGY OF UTERINE CASTS PASSED DURING MENSTRUATION.

The author showed specimens (1) of blood casts,

which consisted of blood that had clotted in the uterine cavity and become moulded to the shape of that cavity, and (2) of endometrial casts, both thick and thin. These all showed a distinct decidual reaction in the stroma.

The pathology of the former (blood casts) was explained as being due to the fact that the endometrium failed to extract the fibrin ferment, either because the hæmorrhage was too profuse or too rapid. The pathology of the latter (endometrial casts) was stated to be due to the fact that there is extensive menstrual decidual reaction, which renders the endometrium much denser than usual. Consequently the blood which cannot break through into the uterine cavity strips up the membrane, either in its superficial parts or throughout its whole depth.

DR. BLAIR BELL read a short communication on the sequel to a case (described at a previous meeting) of bilateral carcinomatous sarcomata of the ovaries. The patient, who is now dead, developed recurrences in the omentum, which, on section, were found to be carcinomatous in nature. This was considered to be conclusive proof that the original tumours consisted both of carcinoma and sarcoma.

DR. E. TENISON COLLINS, of Cardiff, read a paper on DOUBLE RUPTURED ECTOPIC GESTATION.

Cases of simultaneous double ectopic pregnancies are so uncommon that the author thought the specimen shown would be of interest to the section. Mrs. B., æt. 33, was sent down to the King Edward VII. Hospital at Cardiff late on Saturday night, April 7th, 1912, by Dr. Thomas, of Bargoed, who had diagnosed the case as one of ruptured tubal gestation. The patient had had four children, the last $2\frac{1}{4}$ years ago, and two miscarriages, the last being four years ago. The last menstrual period was on February 3rd, or eight weeks before admission. About the middle of March she fell over a five-foot wall in her garden, and three days later was seized with pain in the left side, and the abdomen began to swell. Six days before admission she had slight vaginal hæmorrhage with more pain, and went to bed. Nothing suggesting a decidual cast was passed. On admission the patient was very anæmic, pulse 110, respiration 28, but no marked signs of collapse. There was dulness over the lower abdomen, and on vaginal examination the uterus was fixed in a somewhat solid mass.

On April 8th the abdomen was opened and a ruptured pregnant tube on the left side was found and removed. On examining the right appendages, to Dr. Collins's surprise another ruptured tube was found with a small fetus outside it, and attached by a cord, which broke during removal. After removing the blood clot, the abdomen was filled with hot saline solution and then closed. Professor Emrys Roberts examined the specimens and reported as follows:—

Left Tube.— $6\frac{1}{2}$ cm. long, 3 cm. diameter in centre. Tube showed rupture in middle third. End sealed with blood clots. Microscope shows fetal villi in blood clot removed with it and kept distinct. From left side an amniotic sac $5\frac{1}{2}$ cm. in diameter, but no trace of fetus. Estimated period, seven weeks.

Right Tube.—8 cm. long, $4\frac{1}{2}$ cm. diameter. At outer third ruptured along anterior and upper margin. Well marked amniotic sac with umbilical cord attached. Fœtus 4 cm. long found extruded in blood clot.

The patient made an uninterrupted recovery, and left the hospital on the twentieth day.

The PRESIDENT gave his annual address on the work of the section during the year, in the course of which he discussed the bearing of the maternity clauses of the National Insurance Act on the teaching of clinical midwifery.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD ON THURSDAY, JULY 11TH, 1912.

The President, MR. J. B. LAWFOR, in the chair.

MR. W. H. JESSOP demonstrated Professor Gullstrand's Ophthalmoscope.

The PRESIDENT said it was a wonderful piece of machinery, and afforded a beautiful view, and, with monocular vision, gave a high magnification. The disadvantage was that it almost required a hand-cart for its transference from place to place.

Mr. TREACHER COLLINS showed a case in which an intra-dural tumour of the optic nerve was removed with retention of the eyeball five-and-a-half years ago. The case, he said, showed the value of retaining the eyeball; there was good movement here, and it was altogether better than an artificial eye. It also showed that some tumours were not very malignant in character. Though he did not get all the tumour away, there had been no recurrence. He had been able to get the tumour away without cutting through the bone. The pupil was now gradually dilating.

Mr. W. G. LAWS showed a case of detachment of the retina, with cyst-like protrusion. There was no suspicion of cysticercus.

Mr. P. C. BARDSLEY showed an instrument which he called a "sclerotome," the object of which was to do a trephine operation in one stage. With this instrument there was no danger of losing the trephine disc within the anterior chamber on the completion of trephining.

Mr. CHARLES WRAY said the instrument was liable to get out of order, especially if the knife were inserted with a rocking movement.

A paper was read by MESSRS. BROOKSBANK JAMES and STROUD HOSFORD on

OPERATIVE TREATMENT OF GLAUCOMA.

Reference was made to a note in the Transactions of the Society of October, 1909, in which was described by Mr. James a method of operating upon all cases of glaucoma by cutting through the sclera from without, after having turned down a preliminary conjunctival flap to cover over the linear wound. Since then the operation had been somewhat elaborated by turning out a piece of sclera by the following method. The conjunctiva having been made anæsthetic, and a few drops of adrenalin solution instilled, a large conjunctival flap was turned downwards to the corneal margin. All further bleeding was now stopped by adrenalin. An incision was next made at the limbus, co-centric with the corneal margin, by cutting with the edge of the Graefe knife near its tip, so that the lips of the wound were perpendicular. The paring was proceeded with until a fair depth of wound had been attained. A small puncture was then made, and the aqueous allowed to evacuate itself very slowly. A blunt-pointed Stilling knife was now inserted into this opening, and the wound enlarged throughout its extent. A moderately large iridectomy was then made in the usual way. One then proceeded to turn out a piece of sclera from the upper lip or the angles of the wound, endeavouring to ensure that some of the lining membrane was attached to its under surface. This was laid flat on the surface of the adjoining sclera, and held in position by the conjunctival flap being stroked over its surface. The special points in the operation were (1) the fact that the edges of the scleral incision were perpendicular, not slanting as made by the Graefe or the keratome. (2) It would be noticed that the iris fell backwards much more readily than in an ordinary iridectomy, and did not require the introduction of another instrument into the eyeball to replace it. (3) The scleral flap could be cut by one of two methods. In some of the cases this was done by means of a punch. This, however, was somewhat uncertain, and occasionally punched a piece of sclera clean out, which was not desirable. (4) Another method was to turn outwards by means of scissors or knife a strip from one or both angles of the wound. It this plan were adopted, it was better to outline the strip by marking out its limits almost through the whole thickness of the sclera prior to opening the anterior chamber, as the relaxed state of the tissues when the aqueous had escaped, rendered the proceeding more difficult. Mr. Hosford said he had carried the method out in all his cases of glaucoma except one, and that he did on the periphery of the iris. Whatever method was employed, there was a predilection on the part of the sclera to

close up. Ten out of 38 cases so treated closed up. Of the 38, 28 healed by first intention, and 8 of the remaining 10 healed secondarily. The operation was simple.

SPECIAL REPORTS.

NATIONAL MEDICAL UNION.

A LARGE and enthusiastic general meeting of the National Medical Union was held on Thursday, the 4th inst., at the Onward Buildings, Deansgate, Manchester. Mr. G. A. Wright, the President of the Union, occupied the chair. Numerous letters of regret were read from members who were unable to attend, all expressing their admiration for the work the Union had accomplished. The report of the General Committee, which had been circulated to the members, was taken as read, and the resolutions arising therefrom were debated. At the desire of the meeting the order of these resolutions was altered, and the future activities of the Union were then considered.

Dr. Garrard, of Salford, Dr. Bell, of Bradford (Yorks), and others, spoke in such laudatory terms of the magnificent stand taken by the Union, in guarding the interests of the profession and in getting the British Medical Association to take up the firmer attitude which it has recently adopted, that it was unanimously resolved to carry on the militant work of the Union in watching the interests of the profession, and in strengthening the British Medical Association in its determined opposition to the National Insurance Act, as at present framed. It was remarked that there was a great and distinct need of the Union in the present crisis. Country members were glad to feel that, in a large industrial centre, there was an independent body of men looking after their interests, who could meet at once to consider any emergency which might arise.

The meeting agreed that Dr. J. E. O'Sullivan, of Liverpool, should be recommended as the third Representative of Lancashire and Cheshire on the Council of the British Medical Association. It was stated that he was a general practitioner, and a firm supporter of the policy of the Union. In the recent election he made a splendid fight, and was a good "runner-up." He is undoubtedly the best candidate in the field, and the members present pledged themselves by a resolution to do all in their power to secure his election.

The third resolution was carried unanimously:—"That the medical members of the Advisory Committee should at once resign their positions, as it was both useless and undignified to continue in office." It was pointed out in this connection that the *pourparlers* with the Chancellor of the Exchequer displayed his complete ignorance of medical practice, and that the negotiations were quite illusory.

The fifth resolution was carried with acclamation:—"This Union considers the action of the Chancellor of the Exchequer, in suggesting an inquisitorial investigation into the books of private practitioners, is a piece of unparalleled impertinence, and calls on all members of the Union to refuse to have their books examined by any servant of the Government."

Another resolution which was passed expressed the conviction that it was anomalous that Medical Officers of Health should be asked, or consent to allow themselves, to be elected on Local Insurance Committees. In this connection it was mentioned that at a meeting of Medical Officers of Health, held in London recently, it was proposed by Mr. Smith Whitaker that these Officers, with the aid of assistants, should work the Act. They refused to entertain any such proposal.

Dr. Reynolds thanked the members of the Union for their support in the recent Council election, and stated that he would not give way one iota in his opposition to the Act as it stands, and would unremittingly carry out the determined wishes of the profession.

In view of the recent utterances of the Chancellor of the Exchequer, and other members of the Government, this meeting strongly indicates to the Government, and

to the public generally, the determined attitude of the medical profession. It is quite firm in its decision to take no part in the working of the National Insurance Act until it is amended in accordance with its first demands, and for the benefit of the people whom it is supposed to serve. It is pointed out in the Report presented to the meeting that a money payment in lieu of medical benefits is not an adequate return for the promises contained in the Act; and that the Government will break their contract with the insured if they pursue this policy. It therefore remains with the employers of labour, and the insured, to deal with a Government who have made promises which it is impossible for them to fulfil. The question for them to settle before paying is—can the Government give them any reasonable prospect that the medical benefits promised will be forthcoming? If not, threats of compulsion are useless—the deadlock has come!

FRANCE.

Paris, July 13th, 1912.

NEURALGIC PAINS OF PHTHISIS.

SIMPLE subcutaneous injections of boiled water prove very efficacious in the intercostal pains (stitch in the side) of consumptive patients. The neuralgia ceases after half an hour and the patient is relieved for several days. The quantity of liquid need not exceed one or two syringes. These pains generally derive from patches of dry pleurisy.

For the last four years Dr. Paillard has employed these injections of sterilised water in divers neuralgias, and especially in those of consumptives, with invariable success. He always injected the water *loco dolenti*.

SCIATICA.

Sciatica, as is well known, is a most rebellious affection, resisting frequently every possible treatment: linaments, blisters, actual cautery, electricity, massage, etc., not to speak of internal treatment by quinine, aspirin, salicylate of soda, opium, etc.

It is thus we hail with pleasure any new formula that guarantees some success and we hasten to employ it "while it cures"!

In any case Dr. Turach pretends to cure sciatica nine times out of ten by the following injection:—

Antipyrine, 10.
Cocain, 0.15.
Water, 10.

Inject deeply, *loco dolenti*, one syringe every day or every two or three days, according to the intensity of the pain. These injections are well borne.

The total number of injections does not exceed eight or ten.

LEUCOPLASIA.

Leucoplasmia of the mouth or tongue has been diversely treated by solutions of salicylic acid, bichromate of potash, chromic acid, lactic acid, etc.

Dr. Averinos prefers a preparation of sulphate of copper:

Sulphate of copper, 2 gr.
Glycerine, 10 gr.
Water, 10 gr.

The parts should be well dried before touching the patches with a plug of cotton steeped in this solution. The operation is repeated every day for twenty days after which the applications are suspended for ten days and then renewed.

At the beginning the solution should be diluted by one-half so as not to irritate the mucous membrane by the caustic.

OZENA.

Ozena being proved to be of microbic origin, the treatment should be naturally antiseptic.

Monosulphide of sodium, 10 grms.
Glycerine, 50.
Water, 150.

A teaspoonful in a quart of boiling water for irrigation; a teaspoonful of chloride of sodium should be added to the solution to render it isotonic.

Aristol, 0.50.
Menthol, 0.05.
Essence of geranium, 1 drop.
Essence of vervaine, 11 drops.
Vaseline, 20 grms.

A small quantity is introduced into the nares—morning and evening.

Iodide of sodium, 15 grms.
Arsenate of soda, 0.15.
Water, 300 grms.

A tablespoonful at each repast (2)

Iodine, 1 grm.
Iodide of potassium, 1 grm.
Glycerine, 40 grms.
Essence of verbena, 11 drops.
Essence of geranium, 11 drops.
Water, 10 grms.

Paint the mucous membrane, after local anæsthesia every two days with this solution.

GERMANY.

Berlin, July 13th, 1912

At the Gesellschaft der Charité Aerzte, Hr. Eckert spoke on the occurrence of

LATE NECROSES AFTER TREATMENT BY SALVARSAN.

He showed two children in whom, after salvarsan treatment, marked necroses had developed. The first child was a premature one that was admitted into hospital very much under weight. There were spots on the thighs, the stools were decomposed, green, and a suspicion of syphilis was confirmed by the Wassermann test. The child got the first salvarsan injection on March 22nd; 0.05 dissolved in a c.cm. of fluid were injected into a vein of the head. The injection was extremely well borne, but on the following day sugar was noticed in the urine. A second injection was made on April 13th. On this occasion, 0.04 salvarsan, dissolved in two c.cm. of fluid, were injected. This was not borne so well as the first injection. Vomiting followed, the temperature rose to 37.8, with sugar again in the urine. Two days afterwards, on the distal side of the point of injection—in a vein of the skull—and reaching to the lobe of the ear, there was redness, with swelling. Tenderness on pressure on the part, a feeling of heat. On the day following the inflamed part was very different from the rest; the distal part beyond the point of injection had become necrosed. The healing process went on well, and it was hoped the child would not suffer permanent injury from the treatment. The second child, two years old, was admitted for obstinate chronic weeping eczema; the heart was not sound; the Wassermann test confirmed a suspicion of syphilis. The child received the first injection (0.15 salvarsan in 4 c.cm. of fluid) on March 13th. On the 20th there was a mild urticaria, possibly due to the salvarsan; but one so often met with urticaria in exudative complaints. The second injection of 0.1 in 2 c.cm. of fluid was made on April 4 into the left cubital vein. It was also well borne, the child appeared quite well, left its bed and was lively. Three weeks later petechial hæmorrhages were seen on the dorsal surfaces of both feet, which soon increased in size until they were almost the size of a penny piece. The skin over the part was swollen, red, and tender to the touch. The child was out of sorts, with the temperature raised to 38. On May 2nd similar appearances came into both ankles; at midday there were similar symmetrical hæmorrhages on the middle phalanges of the second and third fingers of both hands. Here the hæmorrhages only reached the size of pin-points.

The cases were not shown for the purpose of discrediting the treatment in any way, as in Heubner's Klinik they had always striven to make it useful in children's cases. The cases had been brought forward, therefore, in order that the causes of the disturbances might be discovered. He would now dis-

cuss the possibility of an explanation of the untoward occurrences.

(1) In both children two injections had been made within about three weeks. The second child had already undergone a course of arsenical treatment in the form of subcutaneous injections of sodium cacodylate. Possibly these might have been not without some influence.

(2) The injections had been made with the salvarsan dissolved in but a small quantity of fluid, and he pointed out that the long period of three weeks between the last injection and the onset of the hæmorrhage was not in favour of any causal connection between the two.

(3) The injections themselves were carried out in a manner quite free from objection. None of the solution could have got into the tissues around the veins.

(4) For an explanation of the necrosis another factor was necessary, and this would lie perhaps in injury of the wall of the vein.

(5) For both cases he could claim that there was no bacterial infection.

(6) As regarded both cases there could not be the least suspicion of embolic origin.

Hr. Heubner thought he was in a position to offer an explanation of the remarkable occurrences, considering arsenic to be a vascular poison. Hr. Heubner, jun., had shown that certain substances—gold, silver, antimony, and arsenical preparations—acted as poisons to the walls of blood-vessels, and specifically damaged their contractile elements. Here it would not be difficult to understand the effects of arsenic in such cases. We knew, as Hr. Blumenthal had told them, that arsenic very quickly entered the blood current. Depôts of arsenic were formed in the tissues, and especially in the liver. What combination of arsenic was thus deposited was not known. It was possible that one form of arsenic and albumen combination was more poisonous than another. As explaining the occurrences in the two cases brought forward only the action of arsenic as a capillary poison could come into consideration. If this were so the form and late appearance of the necrosis would be explained.

Hr. Heubner thought from experiments made by his son with gold, that there was a direct poisoning of the capillaries, in consequence of which the surrounding tissues were no longer nourished, and so became gangrenous.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH UNIVERSITY GRADUATION CEREMONIAL.—In the McEwan Hall, on July 12, the degree of M.D. was conferred on 45 candidates, and the degrees of M.B., Ch.B., on 123 candidates. The usual gold medals, scholarships, and prizes were also awarded. After the ceremony of capping was concluded, Professor Alexis Thomson delivered an address to the new graduates. He said that up to that stage they had followed a beaten track; they had done as they were told—more or less; now they were their own masters. As promoter it was his privilege to offer unsolicited advice, and he had to apologise for the first instalment being of a negative order. These may be described as a series of

DON'TS :—

Don't be in a hurry to decide on your future line of work.

Don't let yourself be tempted to accept an undesirable appointment, although there may be a salary attached to it. Doctors on the whole should beware of salaries. They are usually inadequate.

Don't marry until you have settled down to some definite line of work. An early, premature marriage, he added, is apt to limit the field of selection of work.

The first positive advice he had to give, was to obtain a hospital residency for six or twelve months. There was considerable risk, if they embarked at once

on practice without post-graduate work, of their continuing to be satisfied with the knowledge and the outfit they now possessed. The associations of hospital work tended also to broad-mindedness and diminished the tendency to the development of fads, the pursuit of which was eminently out of place in a doctor. He suggested that when they did go into practice they should be chary of adopting extreme views on debatable questions—such, for instance, as what is the most appropriate diet for a community, or should indulgence in tobacco, or in alcohol, be abolished or encouraged. Doctors were, on the whole, too ready to give advice, whether they knew anything on the subject or not; it was one reason for the almost universal success of Scottish doctors, especially in England, that they were more reticent, and therefore got the credit of knowing more than they did. Living, as we did, in a democratic age, we deplored the fact that nine-tenths of the national sickness was due to ignorance or folly. Preventable disease was pure waste. Unfortunately, the exigencies of our political system were such that, although the supreme importance of the national health was recognised, there was no minister or department of public health to advise the Government in framing legislation. Hence measures, such as the National Insurance Act, of which the principle was unimpeachable, contained provisions detrimental to the moral and material interests of the profession, and indirectly thereby to the public. He would digress a moment to remind them of the dual personality of the doctor. Their training, up to now, had made them individualists, self-reliant, with the aid of books and instruments, to fight disease. But they would not be a month in practice without realising that there was another side to the doctor's life—his relation to the State and the public health. The individualist came quickly up against sociological questions, against laws affecting him as a practitioner in the framing of which he had not a word to say. He thought that in the last year of their studies they should have some instruction on that aspect of their future careers. Fortunately, there was a body which ten years ago formed a branch department of its purely medical and scientific activity devoted to medical politics—the British Medical Association. In recent years, he might say months, this medico-political department had been the only means of expressing the organised advice of the profession on legislation, and it was his duty towards those who were girding themselves for their life-long struggle with disease to advise them to add membership of the association to their armamentarium. Let them also, in their calling, remember the golden rule. So-called medical etiquette was to do to others—both their patients and fellow doctors—as they would desire to be done by.

NATIONAL INSURANCE ACT.—The Edinburgh and Leith division of the British Medical Association have unanimously decided to instruct their representatives at the general meeting to support the motion to break off negotiations with the Government, as no material concession has been made by the Chancellor since February last to the demands of the Association.

BELFAST.

BELFAST MILK SUPPLY.—The Local Government Board inquiry with reference to the application of the Belfast Corporation for an order authorising them to exercise powers of inspection of dairies outside the borough, from which milk is supplied within the borough, concluded last week. Various rural district councils were represented, and it was contended on their behalf that the introduction of another inspecting authority would only lead to confusion in the country, and that a great deal of the contamination of milk was caused in the railway stations. The Town Solicitor, in reply, urged that powers were wanted for inspection only, not prosecution. The consumer of the milk was most directly interested in the supply, and he contended that the Corporation represented the consumers in applying for the order. He believed that the evidence showed that there had been considerable laxity in carrying out the provisions of the Cowsheds Order.

THE LOCAL MEDICAL COMMITTEE.—During the past few weeks an immense amount of solid work has been done in connection with the formation and organisation of the Local Medical Committee in Belfast. A most satisfactory feature of the work is that it is being done by the men who will be most affected by the Insurance Act, and not being left to the officers of the local societies, who are generally young hospital men aspiring to be consultants. The enthusiasm among the general practitioners is very marked, and the number of those who have signed the undertaking promising loyalty to the profession grows daily. There are about 220 practitioners in the city, of whom 185 have already signed. Several have promised to sign, several are absent from home through illness, etc., and only three have actually refused to sign. Even these three protest that they have no intention of acting as blacklegs. A general meeting of the profession will be held on the evening of July 17th to consider further steps.

NORTH DOWN CORONERSHIP.—Dr. Samuel Wallace, of Lisbane, has been appointed coroner in the room of the late Dr. R. C. Parke, of Newtownards. Dr. Wallace graduated M.D., M.Ch. in 1883 in the Royal University of Ireland, and is very popular in the district.

LINDSAY MEDICAL GOLF CUP.—The competition for this cup was recently played on the excellent links of the Royal County Down Club at Newcastle, co. Down, by kind permission of the council. Mr. A. B. Mitchell, of Belfast, entertained the competitors to lunch and tea. Dr. Rankin becomes the holder for the present year, Dr. F. C. Smyth being the runner-up.

MCQUITY MEMORIAL SCHOLARSHIP AT THE ROYAL VICTORIA HOSPITAL.—After the death of Dr. W. B. McQuitty some of his patients, friends, and colleagues raised a sum of money for a memorial to perpetuate his memory. This was handed over to the Board of Management of the Royal Victoria Hospital to found a prize for proficiency in practical work. The first award has recently been made, and Mr. H. P. Malcolm has the honour of being the first McQuitty Scholar. The amount of the scholarship is £30.

DR. CECIL SHAW.—Dr. Shaw's friends will be glad to know that he has recovered from his recent prolonged and severe illness. He hopes to resume work at once, and we join with his friends in hoping that he may soon recover the ground he has lost, and that he may be fit for his duties for many years to come. Dr. Shaw has always taken the greatest interest in the training of the medical student, and in the prosperity of the medical school, and his advice and assistance have been much missed.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

ON THE IMPORTANCE OF TEACHING PEOPLE TO BE SICK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Insurance Act will be of immense advantage to the medical profession. Why? Because it will educate people into being ill.

Nothing is more short-sighted than opposition towards it. It is true that it may, for the first few years, lessen the incomes of some men, but after an interval it will immensely increase the amount of money spent in medicine.

Glance for a second at the sister professions. Does any man suppose for a moment that justice prevails most where there are most lawyers employed? One goes to law, as he imagines, to get justice; but one really goes because he is of litigious instincts, or because it is the custom, or because one's opponent has recourse to law. If the lawyers were offered a capitation fee to defend the interests of their clients, when called in, they would eagerly take it. They know that having the free service of a lawyer would greatly increase the desire to go to law, and that once

the people learned the habit of litigation immense fees would be forthcoming to prominent men.

Consider the Highland crofter, the Irish peasant, and the London City man. At the age of five years the expectation of life of each is almost equal. It will make no notable difference to the life tables if the London man spends £100 a day in doctors—he will surely live as long as the countryman, but from the point of view of the profession what a difference there is!

Probably during a long life the average direct contribution of the Irish or Scotch peasant towards their bit of medicine is one halfpenny for Epsom salts per annum. It may be that the dispensary doctor takes a glance at him during his last illness, but that is about all.

Your city man lives no longer, but he means more to the profession. He is always eating too much, and scarcely a week of his life elapses but he sees some specialist or other. Every season he takes the cure at Marienbad, Vichy, Spa or Wiesbaden. He is a good mark for a hundred guinea operation on his appendix, for a £50 operation on his gall-bladder, for a £25 Wassermann reaction, and a sixty guinea course of salvarsan. Sooner or later he comes under treatment for neurasthenia, and runs the gamut of electrical treatment, mud baths and opotherapy.

First thing in the morning when he opens his eyes, is to take a glass of Hunyadi Water. He then takes a carbonic acid bath and a few lithia tablets. He scrubs his gums with Odol, sterilises his face with carbolic soap, shaves with a patent razor and cures his cut chin with Hazeline. Then he takes his morning tonic and proceeds to breakfast off Quaker Oats and Sanatogen. He uses saccharine in his coffee, and lactic acid bacilli tablets in his milk. Thereafter he liberally doses himself with pepsin and pancreatin. One of his chief topics of conversation is health fads and cures. He knows all about every specialist in Harley Street. A few years ago he attributed all his ailments to nasal catarrh. Later he blamed everything to his appendix. Last year he was sure it was gall-stones. Now he knows himself to be a victim to acute pancreatitis. Next year he will be convinced that the source of all his troubles is hypersecretion from the pineal gland, and the year after he will dread being a victim to the status lymphaticus.

I suggest that the Insurance Act will educate the Irish farm labourer and the Scotch crofter, the struggling shopkeeper and the ailing artisan, into adopting the psychological attitude of the rich city man. Of course they have not as much money to spend—but they can do their best.

After all, the whole aim of our profession for centuries has been to get the people to send for the doctor. The Insurance Act enables them to do it free of charge. Once they get into the habit of using one doctor free, they begin to desire something better, and thus think they can get it by bringing in a second doctor, or a specialist, and paying him. All of which makes for the good of the profession.

I am, Sir, yours truly,

J. C. MCWALTER, M.A., M.D., LL.B.

Dublin, June 30, 1912.

DOCTORS AND THE INSURANCE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If there be any gratitude amongst doctors—which I question—we should thank Dr. Macphie for his letter in the MEDICAL PRESS AND CIRCULAR of July 10th. He shows plainly that the offer of 4s. per annum by Mr. Lloyd George is only political bluff—a strong desire to deal in the cheapest market—even when human lives and human health are concerned (for if the people were cattle there would be an offer of about 40s. per head per annum); and a misleading of Mr. George by the Welsh Colliery doctors. For instance, in Wales a collier pays about 3d. per week for medical services, while the payment of an extra few farthings per week secures medical treatment for wife and children. The term "club doctor" has now

become the subject of public scoff and satire. It has been said that starving doctors have no alternative. But there is an alternative—not to starve.

I would take strong objection to Dr. Macphee's statement regarding the acceptance of 8s. 6d. He neglects to state that this is a minimum only, and that it does not include obstetric and surgical fees, medicines, Sunday and night visits, etc. I feel certain that if a capitation grant be adopted, the fee p.c. should be 15s. The German doctors, after many years' fighting, have been granted the 15s. fee. Why not ourselves? There is any amount of money to pay us. For instance, I have calculated that in the United Kingdom men spend about £175,000,000 yearly on prostitution, £137,000,000 on alcohol, £23,000,000 on tobacco, and £44,000,000 on sports. Surely the public can pay their doctors at a higher rate than they do their prostitutes. Even the Christian Church would cry out "For shame!" to any body of men—M.P.'s or others—who offered a poor Mary Magdalen 4s. a year for sexual services, no matter if she were guaranteed 100 "insured persons." Need one do more than refer to the millions sterling used up yearly in foreign missions for the conversion of Jews, Mohammedans, and the other 800 sectarian bodies. Do let us have a little honesty among ourselves, a little less lying about "the Christlike profession," about how each of us make some thousands yearly. We have been "feeding up" the public with the most romantic untruths about our incomes. "Just run off my feet," says liar No. 1. "Just been out at fifteen confinements last week," says liar No. 2. "Think of retiring next year," says liar No. 3, and so on, until one wishes that Ananias and Sapphira had been sterilised, so that the race of medical and other liars had died out.

If the average medical practitioner will refuse to recognise that everything is now against him, he will soon be wiped out. He is on the down grade, and will reach the bottom if he does not leave off his slinking tactics. Year by year, more and more well-to-do persons go to the (1) Poor-law hospitals, (2) municipal free hospitals, (3) voluntary hospitals, (4) free vaccinations, (5) midwives, (6) prescribing chemists, (7) St. John Ambulance practitioners, (8) medical inspection of school children, and now (9) medical treatment of these and (10) sanatoria. I have nothing but contempt for the doctor whose sole response to a demand for work and unity is, "Oh, damn it! it will last my time all right." This type of doctor must be termed a medical blighter, for he will neither work himself nor give any financial assistance to any medical organisation. In the meantime, let each doctor warn every parent not to put his son into medicine. At present the number entering are falling off, but this must be acutely accentuated.

I am, Sir, yours truly,
ROBERT R. RENTOUL.

Liverpool.
July 12th, 1912.

"UNDER WHICH KING, BEZONIAN? SPEAK OR DIE!"

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On p. 3 of the *Daily Graphic* of Monday in last week appears an article by Mr. Sandow on "The Wonderful Mechanics of Digestion: A Remarkable Contribution to the Literature of Health by the Great Physical Culturist." A most lucid explanation is given of the facts that "all human power comes from muscle"; that "muscle development is power development"; and that "therefore the first step in the treatment of indigestion is the scientific development of the muscular power of all the associated organs." Nothing could be more clear or convincing; but for the benefit of those interested in the further development of this subject Mr. Sandow generously offers a gratis copy of his book, entitled "Indigestion and Dyspepsia," which it will well repay every dyspeptic to peruse carefully from beginning to end. Instead of floundering in a morass of pseudo-scientific matter, the reader is placed in possession of plain facts in plain language, and fully explanatory of the

various physiological processes of digestion. The book also describes the natural method of cure by the Sandow system."

It seems a great pity that before laboriously compiling his lectures on "The Treatment of Dyspepsia," the first of which appears in your issue of July 10th, Dr. Willcox, of St. Mary's Hospital, did not consult the great physical culturist, and learn from him the real fundamental scientific facts of the question. Dr. Willcox is merely an M.D., F.R.C.P.Lond., and has doubtless gone through nothing more than the conventional education and experience that lead to a place of distinction on the staff of a great London Hospital. What is his knowledge compared to that of the Great Physical Culturist? Dr. Willcox's writings suggest that digestion is an extremely complex chemico-physiological process. It may be, he teaches, that owing to simple functional disturbance, or to organic diseases and some failure in the secretions that act upon the food—saliva, gastric juice, bile, or pancreatic fluid. Or again, as Dr. Willcox explains, the subjective symptoms which patients call "indigestion" may be associated with phthisis, with ulcer of the stomach or small intestine, with chronic appendicitis, with hernia, with parasites like tape worm, or with innocent or malignant abdominal growths, and with a score of other diseases of totally different origins. In the light of the teaching of the Great Physical Culturist all this sounds grossly absurd and old-fashioned, and the question arises, would Dr. Willcox be liable to a charge of manslaughter if, through neglect to avail himself of the teaching thus gratuitously offered, he allowed a patient to perish for lack of the "Sandow Treatment." By this treatment we are assured that "the whole health of a patient is steadily built up step by step in a sequence of purely natural changes that involve a whole process of bodily reconstruction. There is no mere attempt to allay what are but the symptoms of disease, but a radical elimination of the causes."

I am, Sir, yours truly,
A VERY SIMPLE PRACTITIONER.

July 11th, 1912.

RESEARCH DEFENCE SOCIETY—APPEAL FOR FUNDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We are of opinion that experiments on animals in this country should be restricted by law, that the present Act should be efficiently administered, and that the utmost care should be taken to ensure the minimum of pain in these experiments.

Some of the anti-vivisection societies have lately adopted methods which are grossly offensive to the public interest. They have opened no less than sixty shops in London and elsewhere. Most of these shops have lasted only a few weeks; but they have had time to spread falsehood, prejudice, hatred and suspicion against scientific research. They have also done harm to small children. It is no light offence to exhibit in public not only brutal cartoons and caricatures, but stuffed animals tied down for operation, while the truth is carefully concealed that no operation is allowed on any animal in this country except under an anæsthetic.

In this connection we would remind the public of the unanimous statement of the Royal Commission:—

"To represent that animals in this country are wantonly tortured would in our opinion be absolutely false."

The excuse is offered for these shops that the appliances displayed in the window are actually supplied by the makers. But if the appliances used in our hospitals were displayed in a shop-window with models of human beings tied down for operation it would be no excuse for such a travesty to say that the appliances had actually been supplied by the makers.

Some of these societies, having wealth at their disposal, are able to rent shops in the most crowded thoroughfares or to attract by the very lavish and rather unscrupulous use of money a large audience.

It seems that an effort is being made to work on the mere liking for horrors, real or sham: that no exhibit is too sensational if it can serve to draw attention and to excite passion.

When we think of the vast multitudes of lives, human and animal, saved from pain, disease and death by discoveries made through experiments on animals, we cannot believe that the present methods of anti-vicevisation societies are acceptable to sensible and honest people.

The only way to fight these methods is to be constantly publishing the facts of the case put before the Royal Commission and embodied in its final report. The Research Defence Society, in the past twelve months, has given more than a hundred addresses and lantern lectures in all parts of the kingdom, and has distributed more than half-a-million pamphlets and leaflets. But there is much more work waiting to be done, if we had the money for it. We therefore appeal for special donations, to be controlled by the Committee of the Society, and to be used solely for such purposes of education as public lectures and distribution of literature. All cheques should be crossed Messrs. Coutts and Co., and made payable to the Hon. Treasurer, Research Defence Society, 21 Ladbroke Square, London, W. We hope and believe that this appeal, in the interest of the public, will be very generously answered.

On behalf of the Society,

We remain, Sir, yours truly,

DAVID GILL,

President.

SYDNEY HOLLAND,

Chairman of Committee.

ROBERT CECIL.

LUKE FILDES.

WILLIAM RAMSAY.

MARY SCHARLIEB.

F. M. SANDWICH,

Hon. Treasurer.

21 Ladbroke Square, London, W.

OBITUARY.

DR. W. T. SHEPPARD, OF LIVERPOOL.

WE regret to record the death of Dr. William Thomas Sheppard, of 64, Durning Road, Liverpool, which took place on the 9th inst. from heart failure, at the age of 64. He was visiting a patient at whose bedside he suddenly collapsed and expired. About six years ago Dr. Sheppard had a serious illness, which had affected his health ever since.

The deceased was born at Keynsham, Somerset, on May 31st, 1848. He graduated M.B., C.M., with honours at Aberdeen University in 1874, becoming M.D. four years later, and he commenced practice in the same year at Durning Road, Liverpool, carrying it on successfully until his death. An active member of the Catholic Blind Asylum Committee, Dr. Sheppard was also one of the founders of Father Berry's Homes, Shaw Street. He was at one time on the committee of the Catholic Truth Society, and was a past-president of the Somerset Society. He took an active interest in free meals for the poor children of St. Anne's Church, Overbury Street, and he was formerly president of the St. Vincent de Paul Society connected with that parish. Much sympathy is felt with his widow and son, who is a member of the medical profession.

MEDICAL NEWS IN BRIEF.

The Welsh Memorial to King Edward.

THE Executive Committee of the King Edward VII. Welsh National Memorial for the Prevention and Abolition of Tuberculosis met at Shrewsbury last week to appoint physicians. Mr. David Davies, M.P., presided. Fifty-six applications were received, and the following eleven appointments were made:—

Dr. James P. Cullen (Sheffield), Dr. H. Hyslop

Thomson (Liverpool), Dr. Gerald Hamilton-Wallace (Westmorland), Dr. E. Fairfield Thomas (Cardiff), Dr. Norman Tattersall (Streatham), Dr. M. J. Johnston (Queen Mary Hospital, Carshalton), Dr. James C. Gilchrist (Ventnor), Dr. Cuthbert G. Welch (Northampton), Dr. N. K. Jordan (Manchester), Dr. D. A. Powell (London), and Dr. Thomas Llewellyn Evans (Midhurst).

It is understood that two of these, Drs. Powell and Welch, have since intimated their intention of resigning the appointments.

Annual Meeting of the Medico-Psychological Association.

THE 71st annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held at the Guildhall, Gloucester, on Thursday last, the retiring President, Dr. William R. Dawson, in the chair. Prior to the meeting, committee meetings were held, and visits were paid to the Gloucester County Asylums at Wootton and Barnwood.

At the annual meeting the officers, Council and Standing Committees were elected. Dr. James Greig Soutar, of Gloucester, was elected President for the ensuing year, and Dr. James Chambers President-elect. Reports from the Council and Standing Committees were received, and a number of honorary members were elected. The retiring President, on behalf of the Association, presented to Dr. Charles Hubert Bond, Hon. General Secretary of the Association, 1906-12, an illuminated certificate expressing appreciation of the energetic manner in which he had carried out the onerous duties of hon. general secretary for the past six years, during which time, owing to the rapid increase in membership, and scope of the association's activities, the work had greatly increased. In making the presentation, Dr. Dawson referred to the great value of Dr. Bond's work on behalf of the Association, and expressed their best wishes for him in his new sphere of work as a Commissioner in Lunacy.

Papers were read by Mr. J. F. Briscoe on "Appendicitis in Asylums"; Dr. McKinley Reid on "Bacteriology of Forty Cases of Diarrhoea, with Special Reference to Asylum Dysentery"; and an adjourned discussion on Dr. Bernard Hart's paper on "A Case of Double Personality" took place.

In the evening the annual dinner of the Association was held at the Guildhall.

Medical Incomes.

THE report of Sir William Plender's inquiry into the income of doctors was issued on the 11th inst. He examined the books for the two years ended December 31st, 1910, and December 31st, 1911, of medical practitioners in Cardiff, Darlington, Darwen, Dundee, Norwich and St. Albans, and obtained information from the superintendents in charge of hospitals, infirmaries and dispensaries serving those towns.

The number of medical practitioners in the six selected areas is 265, and of this number 51 refused access to their records.

The annual gross income derived from visits at patients' houses and attendances at surgeries, less a proportionate deduction for bad debts, is 4s. 2d. per head of the population after deducting therefrom the number of persons attended under contract.

Adding to such income the income derived from patients attended under contract, the average is 4s. 13d. per head of the total population.

The fact that the practitioner's income in Dundee does not include medicines should not be neglected in considering these averages.

The New London Dermatological Society.

THE annual dinner of the New London Dermatological Society was held on July 11th at Pagan's Restaurant. Dr. P. S. Abraham, the President, was in the chair, and there was a good attendance of members and guests, including ladies. After the loyal toasts had been honoured, that of "The Society" was given by Dr. W. J. Midelton, of Bournemouth, which was responded to by the President, who said that up to the present the Society had fully justified its

existence. The health of the guests was proposed by Dr. David Walsh, to which replies were made by Major C. A. Thumm, Dr. Clarence Martin, Editor of the *American Journal of Dermatology*, and Mr. S. G. Kirkby-Gomes. A capital musical programme was provided, the selections contributed by Mr. Sterndale Bennett being especially appreciated.

Royal College of Surgeons of England.

At a meeting of the Council of the College held on Thursday last, the congratulations of the Council were given to the President, Sir Rickman J. Godlee, on his having received a baronetcy, and to Sir John Bland-Sutton and Sir Berkeley Moynihan on being knighted on the occasion of His Majesty's birthday. Sir Frederic Eve, Sir Anthony Bowlby, and Sir Berkeley Moynihan were admitted and took their seats on the Council. Mr. D'Arcy Power, the other newly-elected Fellow, was unable to attend.

Sir Rickman Godlee was re-elected President, and Mr. Clinton T. Dent and Mr. G. H. Makins, C.B., were elected Vice-Presidents for the ensuing year.

The following Professors and Lecturers were elected for the ensuing year at the same meeting:—

Hunterian Professors.—Joseph E. Adams, F.R.C.S., Arthur Keith, M.D., F.R.C.S., Wilfred B. L. Trotter, M.D., F.R.C.S., Kenneth M. Walker, F.R.C.S., and William Wright, F.R.C.S.

Arris and Gale Lecturers.—W. Blair Bell, M.D., M.R.C.S. Liverpool, and C. G. Seligmann, M.D., F.R.C.P.

Erasmus Wilson Lecturer.—S. G. Shattock, F.R.C.S. Arnott Demonstrator.—Arthur Keith, M.D., F.R.C.S.

University of Aberdeen.

At the graduation ceremony held on July 9th, the following degrees were conferred:—

Degree of Doctor of Medicine (M.D.).—George S. Melvin, M.B., Ch.B., Dilkusha, Montrose; John A. Beattie, M.B., Ch.B., St. Pancras South Infirmary, London; Robert M. Chance, M.B., Ch.B., The Infirmary, Peterborough; Andrew J. Shinnie, M.B., Ch.B., Clapham Park, London; David J. S. Stephen, M.B., Ch.B., The Lawn, Lincoln; David M. Baillie, M.B., Ch.B., Chelsea Infirmary, London; Andrew L. E. F. Coleman, M.B., Ch.B., General Infirmary, Stafford; Henry G. Deans, M.A., M.B., C.M.; Adam Gray, M.B., Ch.B., New Southgate, London; George Michie, M.A., M.B., C.M., Johannesburg; William R. C. Middleton, M.A., M.B., C.M., Singapore; James Mitchell, M.B., Ch.B., B.Sc., Brigg, Lincolnshire; Henry W. Smith, M.B., Ch.B., Lebanon Hospital, Asfureyeh, Beyrout, Syria; George I. T. Stewart, M.A., M.B., C.M., F.R.C.S., Ipswich.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—David S. Badenoch, William F. Beattie, Martin M. Cruickshank, Ratan E. Dastur, Elizabeth M. Edwards, Alexander F. Fraser, M.A., William J. S. Ingram, Sydney W. Lund, Edgar A. Pearson, Arthur C. M. Savege, John Shaw, Charles W. Weir, and John Wood.

Diploma in Public Health.—John Brown, M.B. Aberd.; Edward Wood Wood-Mason, M.B. Aberd.; Herbert Stewart Milne, M.B. Aberd.; James George Mutterer, M.B. Aberd.

The John Murray Medal and Scholarship (awarded to the most Distinguished Graduate (M.B.) of 1912) was gained by Richard R. M. Porter, M.A., M.B., Ch.B., Aberdeen.

Trinity College, Dublin.

The following candidates have passed the Preliminary Scientific Examination, Trinity Term, 1912:—

Physics and Chemistry.—Alfred L. Wilson, Eugene J. McSwiney, Patrick Rocks, William E. B. Collins, William J. Dowling, Eric E. Beatty, Charles O. J. Young, Frederick J. Murphy, Thomas W. Sweetnam, Eileen Glenn, Robert A. C. Barrett, Thomas S. C. Black, Sydney V. Furlong, Roland H. Graham, Thos. Stanton, Carl O'Connor, John A. C. Kidd, and Francois A. Joubert.

Botany and Zoology.—Norman L. Bor, Thomas P. Chapman, Charles H. Comerford and Patrick Rocks

(passed on high marks), Patrick B. Moloney, Robert C. B. Ramsay, Alan F. Grimby, Eugene J. McSwiney, Harold MacNeile Dixon, William R. Fearon, Andries A. W. Albertyn, Mortimer McGee Russell, Francois A. Joubert, Frederick J. Murphy, Paul H. S. Smith, Robert T. Stoney, William R. Burns, Thomas J. Lane, James Leahy, David S. Prentice, Benjamin D. Merrin, Charles O. J. Young, Millicent Hamilton Johnston, William J. Hamilton, Francis G. S. Battersby, Joseph G. Bird, Edward Lipman, Cyril R. Littledale, Eileen N. Smith, Walter A. Bullen, and Alan G. Wright.

Intermediate Medical Examination—Part I.—Herbert McW. Daniel, Richard W. Shegog, and Isaac W. Corkey (passed on high marks), Charles D. Pile, John Speares, Eric W. Craig, Edmund D. T. Hayes, Evelyn Ross, Violet M. Deale, Esther V. Adderley, James S. Robinson, George Joughin, Christopher C. Albertyn, Geraldine Murphy, Arthur C. Bateman, Robert L. Vance, George Stanton, William B. Walker, George H. Wood, Clara B. M. Adderley, Eric A. Lumley, Andrew J. Horne, Cecil McL. West, and William B. Cathcart.

Cunningham Medal.—Herbert McW. Daniel.

Purser Medal.—Herbert McW. Daniel.

Final Medical Examination—Part I.—David H. Hadden, Frederick G. Beatty, James H. Fletcher, and Thomas V. Oldham (passed on high marks), Frederick G. Flood, Mabel A. Dobbin, Geoffrey M. Fleming, Charles O'Reilly, Francis A. Roddy, William F. Evans, Charles P. Kelly, William H. R. McCarter, Theodore W. Allen, Rupert C. Lowe, Amy F. Nash, Henry I. G. Rutherford, William S. Boyd, Frank S. Gillespie, Eleanor Taylor, Joseph S. English, George A. Bridge, Reginald H. Jones, John A. MacMahon, Etienne J. Malherbe, Geoffrey A. Hoffman, and Michael J. Ryan.

Final Medical Examination, Part II.—Midwifery.—Georgina Revington, Kenneth K. Drury, Eileen M. Hewitt, and Charles D. Goodenough (passed on high marks), Thomas J. Kelly, James A. Small, William E. Fetherstonhaugh, Richard A. Stewart, Robert Hemphill, Frederick B. McCarter, Robert A. G. Elliott, Joseph A. Maxwell, Edwin F. O'Connor, Edward S. Johnson, William Peyton, Richard S. G. Halpin, and Robert H. C. Lyons.

Intermediate Dental Examination.—Louis E. Wigoder and Herbert J. Wright.

Diploma in Public Health.—Part I.—James T. McEntyre. Part II.—Robert W. Murphy, Arthur F. B. Shaw, Henry J. Keane, and James T. McEntyre.

Conjoint Examinations in Ireland.

The following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, June, 1912.—Miss E. Budd, B. Hiron, and Miss M. McMullen (with honours), T. S. Ambrose, H. M. Alexander, H. E. Andrews, D. Boland, M. Bradley, J. F. Coffey, T. Curran, E. C. H. Ewart, D. H. Ferris, J. A. Fretton, F. B. Harrison, H. Levison, E. McCarthy, T. F. Moran, C. Murray, J. P. Pegum, C. W. Robinson, J. P. Sheridan, and G. C. L. Woodroffe.

Preliminary Examination.—F. J. Bowers, T. J. Clune, J. Cusack, J. L. Farnon, J. Geraghty, F. G. Hall, V. Hawkins, P. Hegarty, J. F. Holmes, L. B. Leonard, M. O'Donnell, M. P. O'Meara, W. Robinson, A. Y. Sloane, R. T. Tate, and H. C. Williamson.

Third Professional Examination.—R. J. Brooks and J. Langan (with honours), R. A. Austin, H. A. S. Deane, G. S. Douglas, F. B. McTavish, J. J. O'Connell, H. O'Donoghue, J. J. Reynolds, M. Shipsey, and F. M. Taylor.

Final Examination.—W. I. Adams, P. J. Burke, U. L. Bourke, H. C. A. T. Cannon, W. H. Condell, M. Garry, J. Good, R. M. Gordon, R. F. Griffith, F. Hannigan, M. J. Hillery, J. M. Horan, W. H. Johnston, T. Kennedy, M. Meehan, F. P. McDermott, C. Molan, H. E. O'Brien, A. A. O'Connor, J. C. O'Farrell, A. J. Patterson, D. P. H. Pearson, J. B. Power, S. Punch, M. Quinlan, Miss B. Sieff, V. J. White, and G. Young.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assisistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

MR. J. M. MAULE (Peckham).—Your communication is interesting, but it is hardly one we could place before our readers, having no special medical connection.

HORSES AND THE HEAT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With the approach of the hottest months of the year, will you allow me to make a practical suggestion with regard to "summering" horses? There seems to be an established idea that horses can be turned out for the summer, and that providing they have sufficient grass and water, they require nothing else. My belief is different, and my practice is this: During the heat of the day, and so long as the flies are troublesome, I bring my horses in at 9 a.m. and keep them stabled till 6 p.m., turning them out again for the night. They have only one small feed at mid-day, and yet they keep in capital condition and are ready for work when required.

W. J. C. NORRIS.

Thakeham, Pulborough, Sussex,
July, 1912.

MR. B. E. (London, N.).—The induction of sleep by means of the electric current was first attempted by Dr. S. Ledue, of Nantes, in 1907, when he published "Le Sommeil Electrique," describing the method and the apparatus employed. The "Ledue current" is an intermittent one, of low tension, and of constant direction. Experiments are still being pursued in order to ascertain the most innocuous manner of producing sleep by this means.

M.B. (EDIN.) (Hants).—Artificial musk is known chemically as trinitrobutylxylol, which is soluble in acetone, benzol or chloroform. We are not aware that it offers any pharmacological advantages over the natural product.

DR. C. D. C. (New York).—Yes, on June 26th, Montreal and Ottawa.

F. J. M. (Dublin).—Letter has been sent to the address in Paris.

FOOT AND MOUTH DISEASE.

A CIRCULAR has been issued by the Local Government Board warning Medical Officers of Health, Inspectors of Nuisances, and Assistant Officers under the Food Regulations that, in view of the serious nature of Foot and Mouth Disease, these officials should exercise the greatest care and strictest vigilance in the supervision of abattoirs and slaughter-houses and places where meat is deposited, prepared or exposed for sale. The parts which require specially careful examination are the heads, tongues and feet. Whenever lesions or signs suspicious of the disease are discovered the officers should communicate at once with the Inspector appointed under the Diseases of Animals Acts, and retain for inspection the suspected parts in order that any further action which may be considered necessary to trace the disease to its source may be taken.

DR. TRACEY.—That is one of the disadvantages of cycling one has to reckon with. A friend who uses both pedal and motor-cycle, says he has found a recently invented puncture remedy, called the "Cyclonier" of distinct service, as it prevents pneumatic tyres becoming deflated when punctured by small objects, such as thorns, nails or flints.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 17TH.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics:—2 p.m.: Throat Operations (Mr. Gillies). 2.30 p.m.: Children's Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Mr. W. Stewart); Clinical Pathology and Pathological Demonstration (Dr. W. H. Dunoan). 5.30 p.m.: Eye Operations (Mr. Brooks).

THURSDAY, JULY 18TH.

ROYAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION) (1 Wimpole Street, W.).—5 p.m.: Demonstration of Cases: Dr. G. Pernot: Mycosis Fungoides d'Embleé. Dr. MacLeod: Specimens of Keloids resulting from Piercing the Ear for Earrings. Dr. Sequeira: Hemorrhagic Lupus Erythematosus, and other Cases.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

Appointments.

DAVIES-COLLEY, H., M.C.Cantab., F.R.C.S.Eng., Fifth Assistant Surgeon to Guy's Hospital.
KINGDON, E. O., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Holsworthy District of the county of Devon.
MATHIAS, C. D., M.B., B.C.Cantab., Certifying Surgeon under the Factory and Workshop Acts for the Tenby District of the county of Pembroke.
STANLEY, E. GERALD, M.B., B.S.Lond., F.R.C.S.Eng., Demonstrator of Anatomy at St. Bartholomew's Hospital.
STEWART, F. J., M.D.Lond., F.R.C.S.Eng., Senior Assistant Surgeon to Guy's Hospital.
SYMONS, C. J., M.D., M.S.Lond., F.R.C.S.Eng., Consulting Surgeon to Guy's Hospital.
TAYLOR, JAMES GEORGE, M.D.Cantab., one of the Medical Referees under the Workmen's Compensation Act, 1906, for County Court Circuit No. 29, to be attached more particularly to Chester, Mold and Flint, and Holywell County Courts.

Vacancies.

Prevention of Consumption Department of the Royal Hospital for Diseases of the Chest, City Road, E.C.—Medical Officer. Salary £250 per annum. Applications to the Secretary.
Westminster General Dispensary.—Resident Medical Officer. Salary £120 per annum, with rooms, gas, coals, and attendance. Applications to the Secretary, 9 Gerrard Street, Soho.
Hampstead General and North-West London Hospital.—Resident Casualty Officer. Salary £140 per annum, with board, residence, and laundry. Applications to A. E. Thomas, Secretary, Haverstock Hill, N.W.
Down County Council.—Medical Superintendent. Salary £500 per annum, with an allowance of £150 per annum, for travelling expenses. Applications to the Secretary, Council Offices, Courthouse, Downpatrick.
Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.
County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, washing and attendance. Applications to Medical Superintendent.
Gravesend Hospital.—House Surgeon. Salary £100 per annum, with board, and residence. Applications to W. Pearson, Secretary.
Ayr District Asylum.—Junior Assistant Physician. Salary £140 per annum, with board, lodging, and laundry. Applications to Dr. McRae, Glengall House, Ayr.
Lincoln Mental Hospital, The Lawn, Lincoln.—Assistant Medical Officer. Salary £150 per annum, with board, etc. Applications to Dr. Russell, Medical Superintendent.
Staffordshire General Infirmary, Stafford.—House Physician. Salary £100 per annum, with board, residence, and laundry. Applications to Richard Battle, Secretary.
Staffordshire General Infirmary, Stafford.—House Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to the Secretary.

Births.

BASHFORD.—On July 11th, at 18 Downshire Hill, Hampstead, the wife of H. H. Bashford, M.D., of a daughter.
GIBBS.—On July 11th, at 92 Church Street, Kensington, W., the wife of Lewis N. Gibbs, M.R.C.S., L.R.C.P., of a daughter.
MINETT.—On July 5th, at 25 Dorset Square, N.W., the wife of Surgeon Percy F. Minett, Royal Navy, of a son.
POWELL-EVANS.—On July 11th, at Berth Ddu, Wimbledon, the wife of David Robert Powell-Evans, M.R.C.S., L.R.C.P., L.S.A., of a son.
PRIDEAUX.—On June 25th, at Nadroga, Fiji, the wife of Engleud Prideaux, M.R.C.S., of a daughter. (By cable.)
SEARS.—On July 10th, at "Point View," Burnt Ash Hill, Lee, S.E., the wife of C. Newton Sears, M.D., B.S.(Lond.), M.R.C.S., L.R.C.P., of a son.
WATSON.—On July 14th, at Wootton Bassett, Wilts., to Dr. and Mrs. Watson—a son.

Marriages.

MENNELL-ALLEN.—On July 11th, at St. James, Norlands, W., James Beaver Mennell, M.D.Cantab., to Elizabeth Walton, younger daughter of Mrs. Allen, of Cazenovia, New York.

Deaths.

HUDSON.—On July 12th, near Nelson, N.Z., the result of a motor accident, James Hudson, M.B.Lond., M.R.C.S.Eng. (By cable.)
SHILLITOE.—On July 10th, at Bournemouth, Alfred Ashby, M.B., aged 49, son of Buxton Shillitoe, of Birch Mount, Sydenham Hill.

NOTES AND COMMENTS.

The B.M.A. Meeting.

THE meeting at Liverpool this year is perhaps more vitally important to the interests of the medical profession than any that has taken place before. Our collective policy as to the National Insurance Act has been virtually decided, and our welfare determined for generations to come. There is one point upon which we think the British Medical Association would do well to reconsider its constitution—namely, the holding of an annual general meeting, open to all members. That is the statutory safeguard of the individual member in the case of all limited companies. It is only of late years that the annual general meeting has been abolished, as part of the policy that has resulted in placing the control of the Association in the hands of a central executive. How completely that has been effected has been shown by the way in which the Council has retained office, although absolutely discredited by formal resolution of an overwhelming majority of members of the Association. The policy of the executive could be publicly discussed without any intervening machinery of delegation at an annual general meeting, and it is to be hoped that the expediency of a reform in that direction will be, at any rate, adequately discussed.

The Imperial Cancer Fund Administration.

THE Imperial Cancer Fund is a nobly conceived attempt to advance our knowledge as regards one of the obscurest of human maladies. The endowment of medical research in the United Kingdom is so scanty in nature and haphazard in distribution that it is a matter of congratulation that ample resources have been placed at the disposal of this particular Fund. It is all the more desirable that the administration of this body be catholic and generous so that all workers who can show a reasonable claim to recognition, may receive from the Imperial Cancer Fund that practical help which is absolutely necessary to the performance of modern scientific research. For a long time past it has been known that only those who work on certain lines and who will consent to sink their individuality in that of the Fund, can hope to share in the advantages of the fine endowment which, after all, has been founded for the benefit of medical research generally, and not to support the views of any particular school of study. Recent events have emphasised the need of a reform in the methods of the Fund. Cancer is still a mysterious problem and the Fund has no more infallibility in method than scores of outside workers, who are hampered by the lack of a well-equipped laboratory and by the prohibitive cost of experimental research. To be narrow and self-sufficient in science is to court

anything but success, and the tendency of the man in the street, whose judgment is not to be altogether despised, is to ask what the Fund has so far accomplished in the discovery of the cause or the cure of cancer. The Radium Institute might, perhaps, find room for some of the earnest workers in cancer, who are unable to find encouragement elsewhere. The field of research in radium is necessarily somewhat restricted, and it should not be difficult to arrange for concurrent work in cancer, the disease which of all others it is hoped radium will control. Meanwhile there seems to be a distinct want for a bibliography of cancer. We doubt if the Imperial Cancer Fund, in spite of its amplitude of resources, has yet grappled with that want. It is hardly necessary to add that we have the warmest admiration for the Imperial Cancer Fund and for the magnificent scientific work that it is accomplishing with a fine spirit of devotion to the highest of human ideals.

Small-pox— Still a Danger.

THE report that small-pox has broken out at Nottingham serves as a reminder that a particularly relentless scourge still lurks within our gates. Three cases were notified at the end of last week, and it will be of interest to watch the progress of events within the next few weeks or months. Nottingham is a densely crowded centre of population, containing many persons unprotected by vaccination and among these the malady may spread like wildfire. Unhappily, since the advent of the "conscientious objector"—introduced by Mr. Balfour's Government—the risk of serious small-pox epidemics has been greatly multiplied. In London there is an army of unvaccinated persons simply inviting attack by one of the most subtle and deadly of all the zymotic infections that prey upon mankind. Certain parts of the Metropolis, such as Whitechapel, would probably be decimated by an outbreak of small-pox. Leicester, again, a city progressive in other directions, has unfortunately for many years been dominated by the anti-vaccinationist craze. One day, in spite of her first-rate sanitary administration, the city may have to recognise the folly of flying in the face of modern medical science—as happened in the small-pox epidemic at Gloucester a few years ago.

The Board of Trade and the Colour Vision Test.

THE sight-testing of sailors, to which Dr. Lynch recently called attention in the House of Commons, is one of national importance. It may be well to add to our note of last week that the Admiralty has for some time abandoned the fallacious Holmgren wool test and adopted Dr. Edridge Green's lantern. It is the

Board of Trade which clings to the exploded method which passes sailors as normal in colour vision when they may be shown to be colour-blind by the lantern test. Surely a Board of that standing should be strong enough to shake off the domination of a small scientific clique which clings to the beliefs and methods of a prior generation. The constitution of the Committee of Investigation into the subject was, to say the least of it, somewhat unfortunate, for it was simply packed with men who were responsible for the adoption of the Holmgren test, and although they have advocated a lantern test, they have made a new one to suit their own requirements. The general view of authorities on the subject is that this lantern is useless for its purpose and unnecessary in view of the existence of a perfect instrument of the kind.

LEADING ARTICLES.

THE PROGRESS OF CANCER RESEARCH.

THE subject of cancer and cancer cures has lately been brought to public notice in a manner that was hardly likely to promote the dignity of scientific research into the subject. Like all work in the experimental or unfinished stage, unprofessional onlookers can never possibly judge the merits or drawbacks of the methods of investigation into such an intricate subject as the aetiology and pathology of malignant disease in all its aspects. In spite of all criticism, however, the work of the Imperial Cancer Research Fund has steadily continued, and, according to the report of the Executive Committee laid before the eleventh annual meeting of the Fund last week, there has been no lack of activity in the technical research carried out under its auspices. One thing stands out clearly in the report, namely, that in order to secure and retain the services of highly trained investigators, it has been found necessary that they should be remunerated at such a rate as to free them from any desire to seek other appointments, and at the same time to enable the Fund to attract workers of originality and skilled training. For this purpose a revised scale of salaries has been recommended and adopted. It is satisfactory to note that the new laboratories provided by the Royal Colleges of Physicians and of Surgeons at their new examination hall in Queen Square have been now completed and occupied, that the general superintendent and his staff are entirely satisfied with them, and that they are a great improvement on those hitherto used. The principal scientific investigations of the year have their basis in the fact that inoculated cancer is found, in a certain proportion of instances, to perish after having attained a certain activity of growth, and have been mainly directed to ascertain the conditions which enable animals to resist the inoculation of cancer, either entirely, so that the graft perishes and the inoculation fails, or by the death of the tumour when it has already taken root and begun to grow. The study of healing in spontaneous and in transplanted tumours shows that the cure for cancer must be sought by obtaining a fuller knowledge

of those properties of the malignant cell which render it susceptible to inimical influences, and not merely by striving to induce these influences in its environment. From small beginnings with tumours easy of attack it is to be hoped that advance will be made, stage by stage, until the cells of the most virulent transplantable tumours and of malignant spontaneous growths may be rendered susceptible to changes in their environment, and liable to extinction through the agency of these changes. even though they cannot be made to succumb to direct attack. The subject of cancer of the tongue in human beings has been selected for special study during the year, and no less than fifty-six specimens have been examined microscopically in consecutive series of sections from one end of the diseased area to the other, with the result that cancer was recognised in chronically irritated areas on the surface of the tongue in earlier stages than had previously been possible. What had formerly been regarded as pre-cancerous conditions were shown to be actually cancer, and were in fact miniature pictures of the more fully-developed disease. The surgical bearings of this investigation have been described by the late Sir Henry Butlin (through whose instrumentality many of the specimens were obtained), and their importance, not only for the treatment of cancer of the tongue, but for all cancerous conditions, need not be emphasised. Further problems for immediate investigation are stated to be the question of the influence of hereditary predisposition to the disease, and also whether immunity or resistance to growth of cancer may be produced by inoculation with tumour or normal tissue from the same animal or from that of another species. The annual subscriptions to the Fund, it is stated, only amount to some two hundred guineas—the price of a small motor-car—which seems utterly ridiculous when the importance of maintaining the high scientific standard of work in this direction is considered. Some of the millions reserved for the treatment of tuberculosis under the National Insurance Act might well have been devoted towards the work of investigation into the causation and treatment of a malady quite as terrible as consumption.

THE NEWSPAPERS AND THE SELECT COMMITTEE ON PATENT MEDICINES.

THE Select Committee of the House of Commons has patiently pursued its labours to the limit of the session, and will doubtless resume after the autumn holiday. Representatives of the British Medical Association have been heard at length, and we understand there is still important medical evidence forthcoming. So far as the evidence goes it furnishes plenty of material for serious consideration on the part of the Committee. Our present purpose, however, is not to attempt any analysis of the position, but to draw attention to the significant action of the lay newspapers with regard to reporting the proceedings of the Committee. The reports so far have been extremely

full and fair in *The Times* and the *Daily Telegraph*, but in other papers, notably the *Daily News*, they have been short and meagre and latterly have been conspicuous by their absence. Hitherto, little or nothing has been said about the share of the newspapers in the patent medicine trade, but last week Mr. Henry Sewill stated the case against them fairly and temperately. His evidence was dismissed by *The Times* in four lines, and by a bare notice in one or two other leading newspapers. It is perhaps expecting too much of human nature to ask them to publish what amounts to a charge of sharing in the profits of a questionable trade. After all the newspapers are within their rights in accepting the advertisement of proprietary drugs just as do the medical journals. The difference between the two is that the medical journals carefully discriminate between what may be called the legitimate and useful, and the unjustifiable and obviously false remedies. Can the lay newspaper editor be blamed if he is not able readily to make a similar distinction? It is to be hoped that the report of the Select Committee will give him guidance upon the point, and will at the same time supply the public with some sort of similar signpost. We have too much confidence in the fine traditions of British journalism to think that once the gross evils of the patent medicine traffic are fully exposed the advertisements will any longer find any wide range of publicity, at any rate, in the better class of journals.

CURRENT TOPICS.

Buxton.

Of the classic spas of the United Kingdom, Buxton is not the least famous. So far as natural beauty of surroundings, not to speak of the medicinal virtues of its springs, is concerned, Buxton compares favourably with the Continental spas of a kindred nature to which our countrymen are wont to flock in large numbers. Now that radio-activity has been demonstrated in the waters of Buxton, the seal of science has been formally impressed upon her charter. The town authorities have recently availed themselves of a new spring having strongly radio-active waters of a temperature of 88° F. A new and handsome Pump Room has been built at the famous St. Ann's Well, the waters of which have been enshrined in successive sheltering halls for many centuries past. A few days since St. Ann's Well was reopened in its twentieth-century dress by the Duke of Devonshire in the presence of a number of townfolk and distinguished guests. Buxton has always enjoyed a high repute amongst the medical profession for the healing virtues of its waters, and it is certain to take a front rank in the tide of prosperity that may be confidently anticipated for our beautiful inland watering-places. It is worthy of note that King George and Queen Mary have taken a keen interest in the revival of popularity of the British spas, which has been manifested ever since the identification of the modern marvels of radio-activity in their thermal waters.

The Sanatorium Benefit and Private Practitioners.

THE Sanatorium Benefit under the Insurance Act is intended to furnish a weapon for tackling the entire tuberculosis problem. Speaking roughly, it may be taken that the treatment given under the benefit will fall into one of two classes—institutional and domiciliary. The dispensary will probably form the centre about which home treatment will focus. It is an important public question how far the private practitioner is to take part in this part of the campaign. It may be assumed that in the great majority of cases it will be he who will make the diagnosis of tuberculosis. That he should also have a prominent part in the treatment of the case is, we believe, essential. This has been freely recognised in the report of the Departmental Committee on tuberculosis (pp. 17, 18):—"The Committee are of opinion that it is of primary importance to the lasting success of any scheme for dealing with tuberculosis that it should enlist the hearty co-operation and stimulate the interest of the general medical practitioners of the country. Their intimate personal relations with patients and their influence in the homes of the people are forces which should be actively enlisted in the campaign against the disease as aids to securing its early recognition and methodical treatment, as well as in promoting the effective after-care of cases of tuberculosis. . . . Again—"In the case, at all events, of insured persons, patients living at home who are treated at or under the supervision of the dispensary, should generally be placed, where they are willing, under the care of some general practitioner, who will carry out the necessary home treatment in consultation with the chief tuberculosis officer of the dispensary, and who will, where the patients are insured persons, be paid out of the funds available for sanatorium benefit." The Committee insists, again and again, that the function of the dispensary as regards treatment should be merely consultative. We find it necessary to emphasise this aspect of the sanatorium benefit, since it is one which is likely to be overlooked by insurance committees unless the point is continually pressed on them.

The Wasted M.D. Thesis.

THE question has often been asked as to what becomes of the thesis required by some of the older universities of their bachelors of medicine before proceeding to the higher degree of doctor. Many of these papers are the outcome of much research and they frequently embody a good deal of original work and observation. A more valuable series of medical monographs can hardly be imagined than the collected M.D. theses of a given university. A few of these, but only a small minority, see the light of the medical press where they are occasionally reprinted *in toto* or in abstract for the benefit of the profession in general or, sometimes, for the legitimate advertisement of the author in particular. The greater number, however, of these interesting documents are doomed to the obscurity of a shelf

in a college library where they remain, for all intents and purposes, as completely buried as if they were in the catacombs. In this sense, therefore, they are wasted because they are inaccessible to the general medical reader. Not so the Paris theses, all of which can be readily seen in London. It is discouraging to the author of a work of this kind to know that his thesis will never, perhaps, be referred to simply because it cannot be got at by those who have been pursuing a similar line of investigation and who wish to know what has been done by other workers in the same field. What is urgently needed is that a copy of every accepted M.D. thesis should be placed in a separate section of one of the great medical libraries, say, that of the Royal Society of Medicine, for easy reference by all. Only in this way can the reproach of allowing so much good work to be buried alive be removed once and for all.

The Old Age Bacillus.

THAT distinguished scientist, M. Metchnikoff, has advanced another method for evading the drawbacks of old age. Everyone knows the butter-milk theory which a few years since kept the dairies busy in all parts of the civilised world, old and new, but of which little is now heard save as a survival in the practice of medical men of conservative tendencies. In spite of the rise and fall of the lacto-bacillus theory its illustrious inventor now comes forward with another and even more ingenious talisman. Old age, it seems, is a sort of chronic poisoning attributable to the absorption of such intestinal products as phenol, indol and skatol. Metchnikoff observed that in white rats the production of these substances is lessened by feeding with beetroot and other sweet foods. He further found that in the dog a special micro-organism, the glycobacter bacillus, turns starch into sugar, which fermenting in turn forms acids that destroy phenol, indol and skatol. The inference is, accordingly, that the glycobacter should be introduced into the human intestine, and we presume that this organism will shortly be placed upon the drug market by the Parisian pharmacists, if, indeed, that has not been already accomplished. Critics on this side of the Channel will probably want to know why dogs, who may be assumed to enjoy a sort of monopoly in the glycobacter bacillus, do not themselves attain old age. On the face of it, M. Metchnikoff's original idea of investigating the life conditions of the long-lived Balkan populations is sound, and the whole matter is well worth a collective scientific investigation from a *posteriori* rather than from a *priori* grounds. Here is a good opportunity for some British or American millionaire anxious to confer a lasting benefit upon the world. Why not found a scientific commission to investigate the causes and conditions of long life in the Balkan principalities?

Quackery in Berlin.

BERLIN is the centre of an empire in which police methods rule supreme, and where laws are multiple, manifold, and minute to the last degree. In spite of this collective State machinery quackery flourishes in that great centre of modern civilisa-

tion with a rankness unrivalled even in the United Kingdom, which permits American and other foreign quacks to exploit its subjects in addition to a vast home industry of a like undesirable kind. According to a recently published official report by Mr. Abraham Flexner, there are in Berlin 3,584 physicians and 1,349 registered "quacks." It says a good deal for the philosophic complexity of the Teutonic mind that it is capable of devising on the one hand a vast network of statute and administrative law against unqualified medical practice and the sale of nostrums, while, on the other, it sets up a register for those whom it is attempting thus rigorously to restrain. Mr. Flexner observes that quackery in Germany has reached unparalleled dimensions. It has become a serious factor in reducing the possible income of the legitimate physician and surgeon. It cloaks immorality and vice. Both the medical profession and the public have suffered grievously from this great social evil. To this it may be added that in the long run the economic loss will fall upon the shoulders of the community. The experience of Germany proves that it is not by laws and by police regulations alone that the pest of quackery will be exterminated. The necessary further condition will probably be found mainly in the education of the people in the laws of wholesome living, and the proper place of medical art in the maintenance of the national and the individual health.

Consumption Sanatoria and Infection.

WE have often commented on the great obstruction which an increasing dread of infection puts in the way of the proper treatment of tuberculosis. The public is unable to distinguish any differences of meaning in the comprehensive word "infectious." A few months ago we had to chronicle how an ignorant agitation, backed, we were sorry to notice, by the carelessly given opinions of medical men who ought to have known better, succeeded in stopping the proposed enlargement of the Royal Hospital for Incurables in Dublin. Doubtless encouraged by this success, the neighbours of Peamount in County Dublin, where Lady Aberdeen proposes to establish a sanatorium, are raising a hubbub. It is, in truth, becoming increasingly difficult to obtain a site for a sanatorium anywhere on account of the mistaken fears of those who live in the vicinity. The only way to overcome this timidity is, we believe, to be strictly accurate in all statements made by experts as regards the danger of infection. To deny all possibility of danger is as foolish as to regard the tuberculous as a danger to all who come near them. The truth is that under proper precautions the danger may be reduced to a minimum. The present position with regard to Peamount is not without its amusing side, in that some of those who are now minimising the danger of infection were loud enough a few months ago in denunciation of the Donnybrook scheme. We hope, however, that, despite the opposition of the ill-informed and the indiscretion of some of her friends, Lady Aberdeen will not be intimidated from carrying out her project of a sanatorium at Peamount.

The Tuberculin Dispensary League.

ONE of the most striking features of the modern campaign against consumption is the growth of the dispensary movement. The tuberculosis dispensary should not be confused with the tuberculin institution, for the former does not necessarily carry out the whole programme of the latter, whereas the tuberculin dispensary claims to treat the poor consumptive by injections of tuberculin as a direct and specific measure. At the second annual meeting of the Tuberculin Dispensary League held last week, under the presidency of Lady Mayo, Dr. Camac Wilkinson, the pioneer of the movement, stated that it had been proved that £350 had enabled more cases to be treated at a dispensary than one of the great consumption hospitals could do in the same time at a cost of many thousands. The primary object of the League is to bring within the reach of the tuberculous poor some simple and effective method of treatment. The chief dispensary at 263 Kennington Road, had become so crowded that it had been found necessary to open it on one or two extra days in the week. Lectures have been periodically given thereat to medical practitioners with the result that tuberculin dispensaries had invariably been started elsewhere upon the lines advocated by Dr. Wilkinson, and it may be noted that seventy per cent. of those under treatment were attending their ordinary work. Such a report is most encouraging, and it is significant that the principal hospitals for consumption have recognised that the system inaugurated by the League cannot be ignored.

Contamination of Bread.

THE attention of the public has been focussed for so long on the dangers arising from unclean milk that there is some chance of everyone getting uncontaminated milk in the near future. But the public is not consistent, nor can it retain more than one idea at a time. Whilst agitation was going on everywhere for the general use of pasteurised milk, the bread of the multitude was handled with unclean hands. It was, and still is, carried through the streets on the tops of bread-vans exposed to all the dust that blows. It is therefore not surprising that many cases of disease can be traced to carelessness in regard to bread. Recently, in the Government Hospital for the Insane in Washington, an attendant who had been caring for a typhoid patient at home, was the means of carrying typhoid to several patients, owing to the fact that he handled the bread supply of the institution. In another large American hospital a typhoid carrier, whose duty was to slice all the bread used in the dining room, had been responsible for seven cases of typhoid within a few months. In the *American Journal of Public Health*, a writer points out that many loaves purchased in shops are covered with hundreds of thousands of bacteria. Of course, the number of bacteria was found to depend largely on the cleanliness or uncleanness of the shop, but more especially on whether the loaf was kept wrapped up or not. In shops of ordinary cleanliness, where the loaves were kept wrapped, the bacterial contamination was not great. *B. coli* and the

typhoid bacillus have been found frequently. This subject requires some fresh investigation in this country.

PERSONAL.

MR. P. P. COLE, F.R.C.S., has been appointed Assistant Surgeon to the "Dreadnought" Hospital.

MR. W. GIRLING BALL, F.R.C.S. Eng., has been appointed Surgical Registrar at St. Bartholomew's Hospital.

MR. T. STANBURY BROOK, M.R.C.S., L.R.C.P., has been appointed Medical Officer of Health to the Chingford Urban District Council.

DR. R. DRUMMOND MAXWELL, M.D., M.R.C.P., F.R.C.S., had been appointed Physician to In-patients at the Queen Charlotte's Hospital.

AMONG the recipients of the honorary degree of LL.D. of the University of St. Andrews last week were Sir Thomas Boor Crosby, M.D., and Sir John Batty Tuke, M.D.

DR. HERBERT GIBBONS WARD, M.D., Ch.B., D.P.H. Vict., has been appointed Medical Officer of Health and School Medical Officer for the Borough of Royal Leamington Spa.

SIR THOMAS CROSBY, M.D., Lord Mayor of London, will attend a meeting of the West London Medico-Chirurgical Society at the West London Hospital tomorrow (Thursday), at 5 p.m., when he will be elected an Honorary Member of the Society.

DR. F. R. PARAKH, M.D., B.S. Vict., L.R.C.P., M.R.C.S., L.M.R.C.P.I., has been appointed Honorary Obstetrician and Gynaecologist to the Parsi General Hospital and Consulting Gynaecologist to the Bacterio-Therapeutic Institute, Bombay.

DR. JAMES LESLIE WATT and Mrs. Watt, of Milbrook, Plymouth, were the recipients the other day of some handsome pieces of silver and an illuminated address as a mark of esteem and respect upon the occasion of their leaving the district for Tavistock.

THE will of Sir Francis Richard Cruise, M.D., D.L., K.S.G., of Dublin, Physician-in-Ordinary to the late King Edward, has been proved in the Court of Probate. His personal estate in the United Kingdom amounted to £23,358. He left £500 for charitable purposes.

PROFESSOR J. LORRAIN SMITH, F.R.S., of the University of Manchester, has been appointed by the Home Secretary to be a member of a Departmental Committee to inquire and report what amendment (if any) of the regulations for the spinning and weaving of flax or tow and the processes incidental thereto is expedient in view of the Report of the Departmental Committee on Humidity and Ventilation in Cotton Weaving Sheds or on other grounds.

ALDERMAN THOMAS HOUGHTON WATERS, M.D., F.R.C.P., of 69 Bedford Street, Liverpool, the "father" of the medical profession in Liverpool, a former President of the British Medical Association, Consulting Physician to the Liverpool Royal Infirmary and the Northern Hospital, first Professor of Medicine in University College, Liverpool, who died in June last, aged 86, left estate of the gross value of £24,070, of which £23,788 is net personalty. He left £100 each to the Liverpool Medical Institution and the British Medical Benevolent Fund.

FRENCH CLINICAL LECTURE

ON

TRACHEOTOMY.

By M. WICART, M.D.

Prizeman and late Interne of the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE operation of tracheotomy is certainly one that may be described as urgent, but in the adult, at any rate, it is not often absolutely of instant necessity. In a child, no doubt, we may have to operate forthwith should the larynx and trachea be blocked by false membranes, and we are, perhaps, too apt to bear these cases in mind in presence of an adult who happens to be threatened with asphyxia. Adults are liable, of course, to many causes of obstruction of the respiratory passages, foreign bodies may find their way into the larynx or trachea, the walls of the larynx may rapidly swell as the result of inflammatory or congestive oedema, or more slowly in consequence of chronic hyperplasia. Neighbouring organs may press upon the air passages, or the natural sphincter of the larynx may suddenly contract and prevent the ingress of air. Every combination of these conditions is possible, and it is for the practitioner to learn to recognise the necessity for tracheotomy, to distinguish between the indications for mere urgency or extreme urgency, and the advantages or the unnecessary risks attending the intervention when not peremptorily called for.

We must be quite clear in our mind as to these points because the *technique* is very different according as we aim merely at making a hole in a few seconds to allow of the admission of air, or, on the other hand, to restore the ability to breathe in presence of laryngeal stenosis. The results, moreover, are quite different, and the *modus operandi* will vary accordingly.

Choice of the Modus Operandi.—Let us take the case of a subject, age 30, whose condition calls for tracheotomy. The air passages can be laid open at any point in the neck: through the thyroid cartilage, the crico-thyroid membrane, the cricoid, in fact, anywhere in the course of the supra-sternal trachea.

Thyrotomy, *i.e.*, an opening in the middle line at the prominence of the thyroid cartilage, is a delicate operation on account of the nearness of the vocal cords. Nevertheless it is indicated in presence of endolaryngeal tumours, and is essentially one to be performed by a specialist.

Inter-crico-thyroid laryngotomy, incision of the crico-thyroid membrane, is an excellent operation in obese subjects, with a puffy neck, infiltrated with air, and in very urgent cases, provided we have at our disposal a proper set of tracheal cannulae.

Crico-tracheotomy is an unsatisfactory operation, which presents no advantage over the preceding, and is open to the objection that it involves the destruction of the best support of the laryngeal canal, entails incision of a cartilage which may be ossified, and exposes us to the risk of fracture of the cartilage when we try to force a passage for the cannula.

High tracheotomy is the most serviceable operation for the practitioner. In very urgent cases it is almost as easy to perform as inter-crico-thyroid laryngotomy, and it is the only operation to be recommended in simply urgent cases, *i.e.*, cases in

which we have time to decide upon the steps to be taken. We shall, therefore, take this operation as the type for adoption.

Low tracheotomy, known as Trousseau's operation, is rarely called for. It is difficult, by reason of the depth of the trachea behind the sternum and the presence of many large vessels below the thyroid, not to mention the thyroid itself. It is an operation that requires a surgeon for its performance, and we need not discuss it.

We will assume that you have just been summoned to a patient who is threatened with asphyxia. Having in a few words ascertained as far as possible the cause of the mischief, you decide forthwith to make an opening into the air passages under the best possible conditions.

You can always attack the same region, with the same landmarks as your guide, in the same position; whatever be the case. The manoeuvres only differ in respect of rapidity of execution. They must be done *presto* if death be imminent, if less urgent map out your field of operation quietly, *festine lente*, so as not to add to the patient's risk.

Place the patient on a table so arranged as to get plenty of light on the neck. Slip a rolled sheet under the shoulders at the root of the neck, thus rendering the median line of the neck prominent. Stand on the patient's right while an assistant maintains the chin in the median line, opposite the sternal notch (fig. 1). If the patient cannot breathe lying down

FIG. 1.

seat him in an arm chair with the head thrown back.

Follow the median line with the index finger from the chin downwards (fig. 2), and try to make out the hyoid bone (more hidden than is thought) and Adam's apple, *i.e.*, the apex of the thyroid cartilage, the most prominent of all; make sure of

it by running the finger a little lower down. Then for half an inch or so we follow the hard line of the thyroid angle and the cricoid cartilage. Select a spot about an inch and a quarter below Adam's apple and you will be about right. You will know

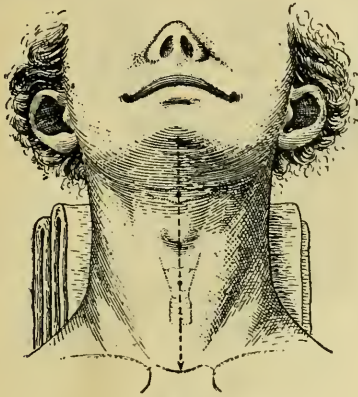

FIG. 2.

this for certain when you have made your incision.

The Rapid Operation.—You are called upon to make an opening at once. The hands, instruments and field of operation having been sterilised (if time permit), make a two inch incision over the marked cricoid point down to the laryngo-tracheal canal, but, however pressed for time, always leave the actual opening for a subsequent incision.

Run over the incision with the left index finger, explore the inter-crico-thyroid space, and if it strikes you as sufficient make the opening there, and if your cannula does not pass readily, quickly cut a notch in the upper margin of the cricoid cartilage. If unprovided with a dilator you can push in a Krishaber's cannula with the point downwards, pressing from before backwards while the anterior surface of the cannula pivots on the upper edge of the cricoid.

If the space turns out to be really too narrow, and the cricoid cartilage too resistant, or should it be that (as is most frequently the case in adults) the obstacle is situated just at this level, at once go below the cricoid, make out the rings of the trachea, and cut through one, two or three rings by plunging the point of the knife a tenth of an inch inwards. Leave the finger in contact with the tracheal wound, which should be well in the middle line, if we are to steer clear of disappointment. Slip the point of the cannula past the finger and turn the point downwards. Your left index will tell you whether it has gone in or whether it has merely slipped along the front of the trachea. This often happens in the absence of previous dilatation. Once the cannula is in place the most important step of the operation is over.

The Slow Operation.—This more deliberate operation only differs from the preceding in respect of the time of the incision, but this is all important if we wish to restore the respiratory function and protect the patient against complications (broncho-pneumonia, which is so often fatal).

The patient is placed as in the previous case. Should he be unable to tolerate hyper-extension of the neck in the recumbent position put him on a chair with the head thrown back, but only when absolutely constrained thereto, and this will not often be the case.

This time you will have time to secure perfect asepsis of hands, instruments, etc. Cover the field of operation with a boiled towel in which a hole has been made and then go ahead. The case may be

urgent and you are unprovided with chloroform or ether. In any case general anaesthesia is to be avoided whenever possible, especially as local anaesthesia with a 1 in 200 solution of cocaine will answer the purpose. We begin by injecting 1 c.c. of renococaine, a strong solution containing five drops of adrenalin (1 in 1,000) and 1 per cent. of cocaine. This is followed by several other injections of the 1 in 200 cocaine solution. In this way the incision is rendered painless and exsanguineous. This last point is of importance in view of the trouble that may be caused by the passage of blood into the trachea and the hindrance to the different steps of the operation.

Determine the formation of white line, puffed as in nettlerash, about two inches long, that is to say, three-quarters of an inch above the lower border of the cricoid, and an inch and three-quarters below. Wait two minutes, then proceed to make the incision. Start this a tenth of an inch below the upper end of the white line and end it the same distance from the lower end. Cut down forthwith to the connective subcutaneous tissue. We then catch sight of some blue lines, for the skin does not bleed owing to the adrenalin. Cut through these blue lines (veins) between two forceps and tie each end. We now reach the white line of the neck which can be recognised by the two bands of muscle fibres on each side. Cut this through and pull the muscles aside with retractors. All these incisions are the same length as the skin incision. The pre-tracheo-cricoid connective tissue then comes into view with, below, the thyroid gland.

With the left index finger in the wound make out the whereabouts of the windpipe. Above you will feel the thick beak of the cricoid and, still higher up, the cricothyroid membrane with, below, the two first rings of the trachea. The third may seem to

FIG. 3.

you to slip from under the finger, but this is really the thyroid which crosses the trachea at this level.

Now examine the bottom of the wound, while the tissues are well retracted. Look for and divide any vessels that cross the trachea and tie them at once. Then, with the aid of the grooved director, you free the trachea from its connective tissue and detach and push down the thyroid body. Should the thyroid cover the upper rings, or if it be adherent, it, like its vessels, must be ligatured and cut through.

We will suppose the three first rings to be exposed and there is no bleeding. You may now make your opening. Puncture with a pointed scalpel just below the cricoid. Push the knife in a quarter of an inch and rip open the three top rings.

Air escapes with a whistle and blood and mucus may be violently expelled. Now is the time to keep cool because the patient begins to struggle. Ram the dilator into the tracheal wound and open it out, whereupon you will be able to slip in your cannula, fitted with its plug. Push it well home.

While this is being done the patient again begins to suffocate and you must make haste to withdraw the plug and substitute the inner tube. Breathing then begins again with the characteristic metallic ring. Should this not be so, should you not feel the warm breath coming freely from the tube, beware, for the cannula may have slipped into the connective tissue. Put a mirror to the patient's mouth; if it clouds it means that air is still passing through the mouth and you must once again introduce the dilator and replace the cannula.

Let us assume that everything has gone well and that the tube is in place. The patient is breathing comfortably. Leave him in the recumbent position, in opposition to the usual practice of allowing him to sit up. It is easier for him to get rid of any blood that may have found its way into the trachea. Get your assistant to hold the cannula in place and tie the tapes attached to it at the side of the neck. Do not tie too tightly, nor on the other hand leave any play, otherwise the instrument might become displaced after you have gone.

Now attend to the skin wound. The lower end should be at least as low as the tracheal wound in order to obviate the occurrence of subcutaneous emphysema. Make sure of this before putting in a stitch below the cannula. Then cleanse the wound and its neighbourhood. A double layer of lint, split in its upper half, is slipped under the tapes on either side so as to make a complete dressing (fig. 4). The last step is to provide for

FIG. 4.

filtering the inspired air. Tie a tape round the neck and fold over it a sterilised compress which falls like a bib in front of the tracheal orifice (fig. 5).

Subsequent Measures.—If blood has entered the trachea keep the patient in bed with the head low. Give him a little diluted spirit, and if there be much shock inject some normal saline solution. On the supervention of the slightest indication of bronchial irritation apply hot mustard poultices to the back and front of the chest, and impregnate the air of the room with water vapour containing two teaspoonfuls of the following mixture:—

Tincture of Eucalyptus ...	200 parts.
Tincture of Benzoin ...	50 parts.
Menthol ...	3 parts.
Camphor ...	6 parts.

The cannula must remain *in situ* while the skin wound is healing, but the inner tube must be cleansed several times a day with boiled water. In very urgent cases should you not have a cannula handy you can make use of a stout rubber drainage tube for the purpose.

When we judge that the time has come for removing the tube, the patient is encouraged to try the effect of stopping the orifice of the cannula with the finger while breathing or speaking. If satisfactory the cannula is taken out and a dressing

FIG. 5.

is firmly applied to the wound. If, however, do what we will, breathing cannot be rendered easy we must insert a cannula of smaller calibre. The wound takes about a fortnight to heal up.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Alexander Zweig, M.D., Physician to the City Asylum, Dalldorf, Berlin. Subject: "The Treatment of Decubitus."

ORIGINAL PAPERS.

NOTES ON A SERIES OF CASES OF APPENDICITIS.

By J. JACKSON CLARKE, M.B., F.R.C.S.,

Senior Surgeon to the Hampstead and North-West London Hospital, and Surgeon to the Royal National Orthopaedic Hospital.

THE following brief notes on a consecutive and inclusive series of cases of appendicitis have been abstracted for me from the hospital notes by Mr. H. W. Littlewood, house-surgeon, and I am encouraged to add to the literature of this much-written-on subject because they enforce the conclusion that only by early operation can the risk of a fatal issue be avoided. The series includes three fatal cases; in one of these—Case XI.—symptoms had existed four days, and diffuse purulent peritonitis was present; in Case XXI, also fatal, symptoms were of four days' duration, and diffuse purulent peritonitis was also present. In the third fatal case—XXXV.—there was a circumscribed abscess, but many adhesions were present, and intestinal obstruction set in, and was not relieved by lateral anastomosis. Every patient who was operated on early recovered, and some who were in a desperate condition of general peritonitis also recovered. The subject of appendicitis is so well-worn that, beyond insisting on operation at the earliest possible moment after the onset of symptoms, technical details are uncalled for. Mention may, however, be made of the ease with which a swab may be left in the abdomen. To obviate this, I have used for years past for private work an operation set of dressings, made according to my directions by Mr. Martindale, of 10 New Cavendish Street. This contains rolls of gauze for packing around areas suspected of containing pus, and to the end of these rolls, which is left emerging from the wound, a pair of catch forceps is attached.

Large gauze swabs for holding back coils of intestine have a long piece of tape attached; this tape hangs out of the operation wound, and to it catch forceps are attached. Since the accidental inclusion of a gauze roll in Case IX. these details have been made part of the routine at the hospital.

CASE I.—Acute Appendicitis. C. S., female, æt. 9. Dec. 2nd, 1910. *History*: Vomiting, 2 days. Pain in R. I. fossa soon after onset, of a colicky nature. Slight constipation. Pain during micturition. *Signs*: Tenderness, rigidity in R. I. fossa. No distension. T. 99.8°. P. 104. *Operation*: Ether; as soon as possible. An incision was made over the appendix, which was gangrenous. No perforations were present and no pus. A drainage tube was put in. *After-course*: Continuous rectal saline. There was slight purulent discharge from the tube until Dec. 14th, when the tube was removed. *Result*: Cure. Left hospital on Jan. 1st, 1911.

CASE II.—Subacute Appendicitis. J. S., male, æt. 12. Dec. 21, 1910. *History*: Acute abdominal pain, especially in R. I. fossa, 5 days. Vomiting. Pain passed off next day, but began on the day following, lasting to admission. Bowel constipated. No vomiting for four days. *Signs*: Deficient movement on R. side of abdomen, rigidity and tenderness over McBurney's point. T. 101°. P. 100. *Operation*: Ether; same day. Incision over appendix, which was found to be thickened and adherent at its tip, but not acutely inflamed. Removal. No drainage. *Course*: Dec. 22 much frothy sputum; acute bronchitis. Small tuberculous focus in R. apex. *Result*: Cure. Discharged Jan. 14th, 1911.

CASE III.—Acute Appendicitis. A. C., female, æt. 27. Feb. 6th, 1911. *History*: Similar attacks on May 1st, Dec. 10th and Dec. 27th, 1910. Occasional mild attacks of pain since Dec. 27. Bowels relaxed. Vomiting. *Signs*: Slight tenderness, rigidity in R. I. fossa. T. 98.4°. P. 80. *Operation*: Ether; Feb. 8. The usual appendix incision. The appendix was found to be closely adherent to the cæcum. It was freed, the stump crushed, and the organ removed. *Course*: Frequent retention of urine after operation. *Result*: Cure. Discharged March 1st, 1911.

CASE IV.—Appendix Abscess. F. B., female, æt. 27. Feb. 24th, 1911. *History*: Pain round umbilicus, constant with exacerbation, 9 days ago. Nausea. Constipation. Pain moved to R. I. fossa next day, where it remained. *Signs*: Tongue dry and coated. Deficient movement of R. rectus. Tenderness and rigidity in R. I. fossa. Distension of lower abdomen. Distinct small lump in R. I. fossa. T. 101°. P. 76. *Operation*: Same day. Gridiron incision. Large amount of pus (very offensive). Marked thickening of cæcum, with abscess below and to the outer side. Appendix not seen. No faecal matter. Peritoneum dried and two tubes through the wound, one to abscess, the other to pouch of Douglas. *After-treatment*: Rectal saline, morphia. *Course*: Offensive discharge for eighteen days. *Result*: Cure. Discharged March 22nd, 1911.

CASE V.—Acute Appendicitis. Local Peritonitis. A. B., female, æt. 50. Feb. 24th, 1911. *History*: Pain of sudden onset 1 day. Nausea, but no vomiting. *Signs*: Marked tenderness, rigidity and distension over whole abdomen. Pain worse in R. I. fossa. Patient declined operation. T. 100°. P. 104. *Treatment previous to operation*: Water only by mouth, enemas, the first of which brought away scybalæ. Patient then became much worse, vomiting much bile-stained fluid on two occasions. *Operation*: CE, ether, open; Feb. 25th, 4.30 p.m. A small median incision, from which a small amount of pus escapes. A second intra-muscular

incision was made over the appendix. More free pus was found. The appendix was not removed; large drainage tubes placed in pelvis and in lateral wound. *After-course*: Bowels moved well after enema on fourth day. *Result*: Wounds healed by March 22nd, and patient left hospital on April 18th.

CASE VI.—Acute Appendicitis. A. L., male, æt. 11. March 2nd, 1911. *History*: Said to have swallowed a whistle a week ago. Twenty-four hours' abdominal pain, generalised, tenesmus and bloody stools. *Signs*: Tenderness and rigidity in R. I. fossa. A small lump was felt in this region. Whistle said to have been seen by X-ray. T. 98.8°. P. 86. *Operation*: CHCl₃ + ether; same day. Incision over appendix, which was found to be inflamed and on the point of perforation. It was removed and the abdomen closed without drainage. *After-course*: Uneventful. *Result*: Cure. Discharged March 25th, 1911.

CASE VII.—Appendix Abscess. M. G., female, æt. 16. March 7th, 1911. *History*: Pain and tenderness in appendix region for 4 days, worse for 24 hours. Bowels open. No vomiting. (Two former attacks.) *Signs*: Great tenderness in R. I. fossa and R. loin. Slight fulness. Rigidity over R. rectus. T. 101°. P. 108. *Operation*: CE; same day. Incision over maximum tenderness. Peritoneum injected and adherent. Pus was found behind the cæcum. The abscess was swabbed out, the appendix being then found œdematous, inflamed and very friable. Three-quarters of an inch was removed without ligature, and the rest was found inaccessible. A drainage tube was passed to the abscess cavity. *After-course*: Drainage for eleven days. *Result*: Cure. Discharged March 30th, 1911.

CASE VIII.—Acute Appendicitis; Peritonitis (local). W. C., male, æt. 6. March 21st, 1911. *History*: 24 hours' sudden acute abdominal pain. Vomiting. Bowels open with enema. *Signs*: Marked abdominal tenderness, especially over the appendix. Rigidity of R. rectus. T. 103°. P. 144. *Operation*: Same day. Incision over the appendix. A few beads of pus were found in the general peritoneal cavity. An inflamed perforated appendix was removed and the stump carbolised. A tube was put to the root of the appendix. *After-course*: 23 days discharged. *Result*: Cure. Discharged April 14th, 1911.

CASE IX.—Appendix Abscess; Fæcal Fistula. E. D., male, æt. 27. March 26th, 1911. *History*: Several previous attacks. Three days ago general abdominal pain, which shifted to the appendix region. Vomiting at onset. Constipation. Pain on micturition 24 hours. *Signs*: Abdomen moves badly. Tenderness, rigidity, distension, and a flat note in the appendix region. T. 101°. P. 94. *Operation*: Ether; same day. Incision over appendix. Peritoneal adhesions. Cæcum much injected. The appendix, which was markedly inflamed and perforated, was behind the root of the mesentery and very inaccessible. There was an abscess cavity containing 4 ozs. of most offensive pus. The appendix was clamped and removed. Two drainage tubes. *After-course*: Two sinuses were left by April 28th. From the upper of these there was an occasional discharge of sanious pus. On May 13th three small sutures were removed from the sinus; on May 15th a gauze swab, which had been left behind at the operation, was found in the depth of the wound. On May 31st blood appeared in the motions and diarrhoea followed irrigation of the wound. From June 1st to June 7th a small fæcal fistula was present. *Result*: Two dry pin-hole sinuses on discharge on July 10th, 1911.

CASE X.—Acute Appendicitis. E. J., female, æt. 46. April 5th, 1911. *History*: Three days ago

a sudden, severe pain in the R. I. fossa, with vomiting and constipation. (Several similar attacks previously.) *Signs*: Tenderness higher than usual in R. I. fossa. Rigidity. T. 99.7°. P. 104. *Operation*: Next day. Incision through R. rectus below umbilicus. Very fat subject. Inflamed appendix, with ulceration of the tip. A concretion in its middle. It was ligatured and removed, and the stump carbolised and invaginated. No drainage. *After-course*: Uneventful. *Result*: Cure. Discharged April 28th, 1911.

CASE XI.—Acute Appendicitis; Gen. Peritonitis. J. S. male, æt. 10. April 10th, 1911. *History*: 24 hours' abdominal pain. Vomiting. Bowels open. (Pain after eating ice-cream four days ago.) *Signs*: Poor movement. Tenderness, rigidity, and a small lump were found in R. I. fossa. Appearance very toxæmic. T. 103°. P. 128. *Operation*: CHCl_3 + ether; at once. Incision over lump. Free pus in peritoneal cavity. An abscess was found on the outer side of the cæcum, and the appendix was found to be red, swollen, perforated, and containing two concretions. It was removed. Tubes to appendix and the pelvis. *After-course*: Continuous rectal saline. Delirium. Frequent vomiting next day, and rigidity, but no distension. Patient gradually sank and died on April 27th, 1911. *Post-mortem*: Diffuse purulent peritonitis.

CASE XII.—Acute Appendicitis. L. C., female, æt. 56. April 23rd, 1911. *History*: Seven days' pain in R. I. fossa, worse for three days. Vomiting once three days ago. Constipation. *Signs*: Tenderness and rigidity over appendix. A distinct lump can be felt. T. 101.8°. P. 130. *Operation*: CHCl_3 . Same day. Incision over lump. Lymph and turbid fluid found in peritoneal cavity. The appendix was long, inflamed, œdematus, kinked on itself and adherent at its tip. It was removed. Many peritoneal adhesions. A tube was left in. *After-course*: Uneventful. *Result*: Cure. Discharged May 24th, 1911.

CASE XIII.—Acute Appendicitis. Gen. Peritonitis. W. H., female, æt. 13. May 2nd, 1911. *History*: Abdominal pain 9 days. Sudden collapse to-day. *Signs*: No respiratory movement of abdomen. General rigidity more marked in R. loin and R. I. fossa. General tenderness. T. 104.4°. P. 124. *Operation*: Same day. A vaginal examination was negative. Incision over McBurney's point. A little pus and coffee-coloured serum escaped. Odour suggested B. Coli. One tube was inserted. Child was returned to ward. *Course*: Propped up in bed. Next day the pulse was 120. Temperature 98.6. No pain. Good movement of upper abdomen. Some dulness on R. side. At 5 p.m. of the same day she again became rapidly worse. General rigidity and tenderness. T. 102°. P. 120. *Second Operation*: One median, two lateral incisions, with posterior counter openings, and another opening in L. lower abdomen. The lesser sac was also opened. Pus was present everywhere but in the lesser sac. The appendix was found and removed. There was a perforation near its free end. *After-course*: Pituitary Extract 10m., morphia, rectal and then subcutaneous saline. On May 5th the tubes were changed for smaller ones under an anæsthetic. Hot saline irrigation of peritoneum and bowel. The tubes were irrigated twice daily until May 23rd, and all tubes were out on June 1st. *Result*: Cure. Discharged June 15th, 1911.

CASE XIV.—Appendicitis; Salpingitis. E. H., female, æt. 43. May 22nd, 1911. *History*: "Sent up as acute appendicitis." *Signs*: Tenderness and rigidity in R. I. fossa. T. 101.2°. P. 104. *Operation*: The appendix was found, on immediate operation, to be surrounded by a few adhesions. The R. Fallopian tube was found to be distended

with blood, and, on being clamped, tore off close to the uterus. The distal end was too adherent for removal, and a piece of gauze was put down to the cut end, and left *in situ*, together with a large drainage tube, and the wound closed. *After-course*: Vomiting and flatulence, relieved by turpentine enemata and rectal irrigation. *Result*: Cure. Discharged June 27th, 1911.

CASE XV.—Acute Appendicitis. R. S., male, æt. 3½. May 31st, 1911. *History*: Twelve hours' acute abdominal pain, vomiting, and the passage of blood and mucus per rectum. A definite swelling was felt under the liver by the doctor who first saw him. *Signs*: R. I. fossa seemed empty, but no tumour was felt elsewhere. There was some fulness on rectal examination and bright red blood was found on the finger-stall. T. 100.3°. P. 134. *Operation*: CHCl_3 + CE; at once. A highly inflamed appendix was found and removed, but no sign of intussusception. *After-course*: Some stitch supuration, but otherwise uneventful. *Result*: Cure. Discharged June 14th, 1911.

CASE XVI.—Sub-acute Appendicitis. T. R., male, æt. 48. June 14th, 1911. *History*: Two days' R.-sided severe abdominal pain, chiefly at distal border. *Signs*: T. 99.1°. P. 76. R.-sided tenderness. *Course*: In bed and on light diet for a week; pain diminished. A fortnight after admission, pain (of a mild, constant nature) moved to R. I. fossa. Leucocyte count 5,200. *Operation*: CHCl_3 + CE; incision over appendix. Very fat subject. The cæcum was inflamed. The appendix was congested, with a few adhesions, and contained a small terminal concretion. It was removed. No drainage. *After-course*: Sub-articular suture yielded. *Result*: Cure. Discharged July 22nd, 1911.

CASE XVII.—Appendix Abscess. D. N., female, æt. 3½. July 2, 1911. *History*: Vomiting ten days ago. Abdominal pain eight days. Slight diarrhœa. *Signs*: Slight rigidity of R. side. Tenderness in R. I. fossa. Under an anæsthetic a moderate swelling could be felt. T. 101°. P. 160. *Operation*: CE + ether; at once. An incision over McBurney's point gave exit to a large amount of foul pus. An abscess cavity, in which was found concretion ½ in. by ¼ in., was drained, without search for the appendix. *After-course*: Glucose saline per rectum. Fowler position. *Result*: Cure. Discharged July 25th, 1911.

CASE XVIII.—Acute Appendicitis. E. P., male, æt. 16. Sept. 6th, 1911. *History*: Twelve hours' pain in R. I. fossa, with headache and sore throat. No vomiting. *Signs*: Rigidity and tenderness over lower part of R. rectus. T. 103°. P. 100. *Operation*: CE + ether. An inflamed appendix, round which were a few adhesions, was removed, and the abdomen closed without drainage. *After-course*: Uneventful. *Result*: Cure. Discharged Sept. 25th, 1911.

CASE XIX.—Sub-Acute Appendicitis. E. T., female, æt. 28. October 5th, 1911. *History*: Six hours' general pain of sudden onset. Vomiting on evening before admission. *Signs*: No local symptoms, but slight rigidity of R. rectus. T. and P. normal. At 15 hours from admission, definite tenderness in R. I. fossa. *Operation*: CHCl_3 , CE. At once. A slightly injected appendix with recent adhesions was removed. A connection was found in its tip. No drainage. *After-course*: Uneventful. *Result*: Cure. Discharged October 26th, 1911.

CASE XX.—Gangrenous Appendix, General Peritonitis. T. H., male, æt. 8½. October 24th, 1911. *History*: Twenty-four hours' occasional vomiting. Sudden general pain one hour. Pain in R. testicle. *Signs*: Face anxious. Thoracic breathing. Slight

distension, with tenderness and pain round umbilicus and over R. scrotum. Per rectum a slight bulging behind. T. 98.4°. P. 156. *Treatment*: Enemata and fomentations. No vomiting, decrease of pulse rate. *Operation*: Ether 26 × 12. Batter's incision. Free foul pus was found. The appendix was gangrenous and perforated. No adhesions. Removal. Five tubes were put in. Saline irrigation. *After-course*: Two hourly irrigation. Continuous rectal saline. Some vomiting. *Result*: Cure. Discharged November 28th, 1911.

CASE XXI.—Gangrenous Appendix. General Peritonitis. A. G., male, æt. 24. October 25th, 1911. *History*: Vomiting four days ago, which had gone off next day, to reappear on admission. General pain four days. Constipation. *Signs*: No movement. Rigidity and intense tenderness, especially at umbilicus. T. 100°. P. 154. *Operation*: CE + ether. Five hours after admission. Foul free pus. An appendix converted into a greenish slough, was removed. Openings and counter openings, seven in all. Irrigation with saline. *After-course*: Continuous saline and glucose. In spite of a temporary improvement, patient ultimately sank. *Result*: Death, October 31st, 1911.

CASE XXII.—Appendix Abscess. C. H., male, æt. 25. November 23rd, 1911. *History*: Three days' pain in upper part of abdomen, with sickness. Taken to a home on the third day, and for the six days following was better. Transferred to hospital. *Operation*: CE + ether. 9th day. A well-localised appendix abscess was found. The appendix, which was gangrenous, was removed. The mesentery was sloughy, and much capillary oozing was present. Counter opening on right and drainage. *Treatment*: Morphia. Continuous saline and glucose, and the Fowler position. *Result*: Cure. Discharged January 1st, 1912.

CASE XXIII.—Recurrent Appendicitis. M. H., female, æt. 31. Dec. 10th, 1911. *History*: Many previous attacks extending over four years. Eight days' pain in lower abdomen of sudden onset. Vomiting. Constipation. Pain gradually, but severely. *Signs*: Some tenderness in R. I. fossa. T. 98.4°. P. 98. *Operation*: Ether; at once. 1 in. incision. The appendix was removed, and the wound closed without drainage. *Result*: Cure. Discharged Jan. 7th, 1912.

CASE XXIV.—Recurrent Appendicitis. E. H., female, æt. 33. Dec. 11th, 1911. *History*: Previous attacks. Slight pain in R. I. fossa for three weeks. Constipation. *Signs*: Tenderness, rigidity general, especially marked over appendix. T. 99.8°. P. 96. *Operation*: CE, ether. The appendix was found to be congested, and contained several irregular, hard, black concretions. *After-course*: Uneventful. *Result*: Cure. Discharged Jan. 8th, 1912.

CASE XXV.—Appendix Abscess; Int. Obstruction. A. F., male, æt. 5. Dec. 14th, 1911. *History*: Eight days' acute pain of sudden onset. Vomiting. Constipation. Pain on micturition. *Signs*: Tenderness and absence of movement all over. Rigidity on R. side. A swelling was felt per rectum. T. 100°. P. 100. *Operation*: Ether; at once. Median incision. Peritoneal adhesion. Circumscribed foul pus found. Appendix not seen. *After-course*: Continuous rectal saline. The condition improved for thirteen days, when signs of peritonitis appeared. *Second operation*: Dec. 28th. The appendix was found. Very inflamed. It was removed and the stump carbolised. No peritonitis, but some enteritis. *After-course*: Signs of consolidation in left lower lobe next day. Vomiting set in, and on Jan. 2nd, 1911, complete obstruction was found, with fæcal vomit. *Operation*: Same day.

A lateral anastomosis was made, but did not relieve the vomiting. *Result*: Death, Jan. 2nd, 1911.

CASE XXVI.—Acute Appendicitis. M. C., female, æt. 22. Dec. 22nd, 1911. *History*: Several attacks previously. Twenty-four hours' acute pain of sudden onset. Vomiting marked. *Signs*: Great tenderness in R. I. fossa. Rigidity. T. 99°. P. 94. *Operation*: Ether; next day. No pus. Appendix very swollen and on the point of perforation. Few adhesions. Tube in loin. *After-course*: Uneventful. *Result*: Cure. Discharged Jan. 20th, 1912.

CASE XXVII.—Sub-acute appendicitis. G. B., male, æt. 30. Feb. 8th, 1912. *History*: One week constipation, with pain in lower abdomen. *Signs*: Tongue dirty. Tenderness and rigidity in R. I. fossa. T. 98.4°. P. 68. *After-course*: After five days tenderness in R. I. fossa was the only symptom. Operation was suggested, but refused by the patient. *Result*: Cure. Discharged Feb. 14th, 1912.

CASE XXVIII.—Acute Appendicitis. C. H., male, æt. 54. March 30th, 1912. *History*: One previous attack. Two days' general pain, especially in R. I. fossa. Pain at beginning of micturition. *Signs*: Slight tenderness and very slight rigidity in R. I. fossa. Movement fairly good. T. 100.8°. P. 66. *Operation*: Within 3 hours. A gangrenous and perforated appendix was found, with a concretion loose in peritoneal cavity. Flakes of lymph, but no pus. Removal and inversion of stump. Drainage. *After-treatment*: Continuous saline. Fowler position. *Result*: Cure. Discharged April 23rd, 1912.

CASE XXIX.—Recurrent Appendicitis. M. M., female, æt. 27. April 2nd, 1912. *History*: Four previous attacks. Pain in R. I. fossa, with vomiting and constipation beginning three weeks ago. *Signs*: Slight tenderness in R. I. fossa. T. 99°. P. 100. *Treatment*: Rest in bed, with light diet for eight days. Tenderness disappeared. *Operation*: Intravenous ether. Old adhesions between appendix, cæcum, surroundings were found. The organ was removed and the stump inverted. No drainage. *Result*: Cure. Discharged May 1st, 1912.

CASE XXX.—Acute Appendicitis. C. B., female, æt. 19. April 25th, 1912. *History*: One previous attack. 36 hours' abdominal pain, especially in R. I. fossa, with vomiting, pain on micturition and constipation. *Signs*: Tenderness and rigidity in R. Iliac fossa. No mass. T. 100.2°. P. 112. *Operation*: Battle's incision. A very friable, almost gangrenous appendix, without perforation. Ligation with silk and removal. Many recent adhesions. Large drainage tube. *After-course*: A sinus was left for four weeks. Marked hysteria. *Result*: Cure. Discharged May 24th, 1912.

CASE XXXI.—Acute Appendicitis. C. B., male, æt. 25. May 6th, 1912. *History*: Three days' pain in R. I. fossa, with vomiting. *Signs*: Tenderness in R. I. fossa, with rigidity. T. 98°. P. 96. *Operation*: C.E., same day. The pelvis was found full of thin pus. The appendix was swollen and soft. It was removed. Drainage of stump and also of recto-vesical pouch. *Result*: Cure. Discharged June 15th, 1912.

CASE XXXII.—Sub-acute appendicitis. C. W., female, æt. 18. May 10th, 1912. *History*: Two previous attacks. Ten days' pain in R. I. fossa, with slight constipation. *Signs*: Tenderness and rigidity over limited area in R. I. fossa. T. 99.8°. P. 80. *Treatment*: Rest for twelve days, with light diet. Tenderness disappeared. *Operation*: Intravenous ether; usual oblique incision. The appendix was injected with a few filmy adhesions, and contained a small concretion. It was removed, with

inversion of the stump. *After-course*: Next morning a catheter specimen of urine showed presence of blood in fair amount. This continued for forty-eight hours and then ceased. No other symptoms. Microscopically, corpuscles were present. *Result*: Cure. Discharged June 10th, 1912.

CASE XXXIII.—Acute Appendicitis. A. B., female, æt. 28. May 10th, 1912. *History*: Thirty-six hours' severe pain in R. I. fossa, with vomiting. Constipation and pain on micturition. *Signs*: Dirty tongue. Tenderness and rigidity in R. I. fossa, extending just across mid line. T. 100.8°. P. 108. *Operation*: CE; at once. Free pus of a yellow colour was found. The appendix was gangrenous, but showed no perforation. It was removed and a cuff of muscular coat drawn over the stump. Drainage of the stump and pouch of Douglas. *After-course*: Uneventful. *Result*: Cure. Discharged June 8th, 1912.

A CASE OF THE HEROIN HABIT. (a)

By J. ODERY SYMES, M.D.,
Physician to the Bristol General Hospital.

HEROIN, or diacetyl morphia, is chiefly used in this country as a sedative in cases of troublesome cough, and is generally given as the hydrochloride in a mixture. I am informed, however, by Messrs. Burroughs and Wellcome that it is largely used at the present time hypodermically, chiefly, I imagine, for the relief of pain or the control of asthma. It is desirable, therefore, that medical men should know that there is a grave risk of a patient using this drug contracting a heroin habit similar to the morphia habit. Several French writers (b) have drawn attention to this point, and from their experience with cases of heroin mania they are convinced that the effects of this drug are more profound than those of morphia, and that the suppression of the habit is more difficult, more dangerous, and more painful.

Duhem, who reports upon seventeen cases of heroin mania, says that in the process of cure the chief danger is that of respiratory failure, which comes on without any preliminary failure of the heart. Respiratory failure is particularly apt to occur in cases in which the drug is withdrawn too rapidly. Amongst other symptoms during the period of cure he notes hallucinations and delirium, periods of emotional excitement, sleeplessness, headache, generalised pain, and the very slow return to normal health and weight. The dose of heroin in the cases reported varied from 1 to 5 grains a day.

A case has recently come under my care in which the patient was supplied by a medical man with a hypodermic syringe and a supply of heroin hydrochloride tablets to be used for the relief of pain, and was assured there was no danger of contracting a habit from its continued use. The patient, a lady of 39 years of age, whilst staying at a well-known spa, was seized with neuritis in the right arm. As other remedies failed to give relief, the doctor gave a hypodermic injection of 1-12th grain of heroin hydrochloride, and directed that the nurse should repeat the dose whenever the pain recurred. The first effect of the injection was to relieve the pain, but half an hour later vomiting commenced and continued during the night. This was late in 1906. As the pain continued, the injections were repeated, first by the doctor, then by the nurse, and later by a relative, and the dose was gradually increased to $\frac{1}{4}$ grain three or four times a day. During the next two years the

patient made ineffectual attempts to break off the habit. In 1907 she learned to use the hypodermic syringe herself. From this time the habit gradually became more confirmed, and the dose increased, until at the time of her breakdown, in October, 1911, she was taking between 4 and 5 grains in the twenty-four hours. The daily allowance never exceeded 5 grains.

With regard to the effects of the drug, I cannot do better than describe some of these in the patient's own words, for she is an observant woman of education and refinement. Even after the first dose there was "a feeling of excessive fidgetiness, which seemed to creep right up from the very lowest part of the body (the womb), making me so terribly restless that I could not keep my legs still for a moment. This particular feeling increased maddeningly until I had the injection again, when I felt immediately relieved and blissfully comfortable for about $2\frac{1}{2}$ to 3 hours." It was the recurrence of these feelings which led to the repetition of the drug throughout. Gradually the patient's health began to fail; she became thinner, less able to take physical exertion, depressed and seedy. The appetite was very poor, and she noticed a peculiar salt taste in the mouth when the drug was withheld; occasionally she had attacks of vomiting, and constipation was most troublesome. The catamenia became at first irregular and scanty, and finally ceased. She had never been a good sleeper, but since taking heroin this had become much worse, and she had recourse to drugs (chiefly veronal) to induce sleep. If the interval between the injections of heroin was too long she "felt wretchedly fidgety and uncomfortable, and people and things seemed to go farther from me as I looked at them, and at times I felt almost lightheaded." If the dose was increased too rapidly it gave rise to palpitation and excitement. Amongst other symptoms noticed were increased sensibility to sounds and loss of recuperative power after small injuries, such as cuts; another most troublesome symptom was difficulty in starting micturition. There were never any symptoms of respiratory failure, oppression of breathing, etc. The patient says that whilst taking the drug (although previously extremely subject to colds) she never sneezed or coughed, nor did she ever catch a cold during the whole five years.

The relief given by the injections was instantaneous, but these had to be repeated at shorter and shorter intervals. The patient describes herself as having felt "bucked up," both physically and mentally, keener sensed, calmer, happier in mind, and more ready and able to undertake the exertion entailed by golf, bicycling, roller skating, or walking immediately after taking the drug. There was no marked mental or moral failure. Finally, in October, 1911, when taking about 5 grains of heroin a day, she was seized with a violent attack of vomiting and prostration with alternately shivering and perspiring. She was unable to move from her bed, and the habit being discovered, an attempt was made to break it off by gradually tapering the dose. Six weeks from the commencement of treatment the dose had been reduced from 5 grains to 4-50th of a grain a day. The chief difficulties had been sleeplessness, restlessness, emotional outbursts, tachycardia, loss of appetite and prostration. The patient was at the time walking out of doors, and the mental condition was normal. Any attempt to reduce the heroin beyond 4-50ths of a grain, although unknown to the patient, gave rise to great discomfort and increased emotional excitement. I therefore substituted $\frac{1}{8}$ th grain of morphia twice a day, and decreased this amount

(a) Read at a meeting of the Bath and Bristol Branch of the British Medical Association, March 25th, 1912.

daily. With the substitution of morphia the restlessness disappeared, and by the end of the eighth week hypodermic injections of sterile water only were employed. During the last week of the cure she suffered from a severe cold, the first for five years.

At the present time, six months from the commencement of the cure, the patient is in splendid health, and professes to have no craving for the drug. Sleeplessness, which has been a troublesome symptom throughout the cure, is relieved by the use of adalin, and this drug is still occasionally used.

PSYCHOGENESIS AND INTERNAL SECRETIONS: EXPERIMENTAL DATA AND PATHOGENESIS.

By TOM A. WILLIAMS, M.B., C.M.EDIN.,

Neurologist to the Epiphany Dispensary, Washington; Foreign Corresponding Member of the Neurological Society of Paris, and of the Psychological Society of Paris, &c.

WE know very little with certainty about the pathology of hyperthyroidism or disorders of the adrenal system.

The importance of rest in the treatment of these cases is emphasised by most writers, as the conditions present are supposed to depend upon overstrain.

Now, it is very evident that it is not physical overstrain that is meant. That mental overstrain can produce these syndromes I very much doubt; but that emotional overstrain may be the prime factor in such cases is an explanation to be seriously thought of, in view of the experimental facts which follow.

It has recently been shown, through a brilliant experimental research by Cannon, of Boston, that the emotion of fear in animals is capable of stimulating the flow of adrenal secretion. He demonstrated that in frightened animals the blood from the adrenal vein is so rich in adrenal substance as to be capable of inhibiting peristalsis in an isolated strip of intestinal muscle. This is due to the presence, in appreciable amount, of adrenal substance, since contact of the latter, in a 1:1,000,000 solution, with the intestinal strip will also inhibit peristalsis.

We knew that the emotion of fear could inhibit gastric secretion; and Pawlow has shown that certain emotions of anticipatory joy can induce a flow of this secretion. Crile has shown, experimentally as well as clinically, that the emotion of fear increases the thyroid secretion; he demonstrated this clearly in certain cases—not necessarily, however, in normal individuals.

Although we have been in the habit of regarding the autonomic nervous system as rigidly autonomic, these experiments show that the sympathetic fibres are somewhat under cerebrospinal control, because in each of the experiments the autonomic symptoms have occurred in virtue of the impressions upon the cerebrospinal nervous system.

It is reasonable to suppose that fear, which, when acute, such experiments have shown capable of exciting the autonomic nervous system and the glands thereto attached, may, when it takes the form of a chronic fear, also produce, less abundantly but to an extent clinically manifest, an overaction of the autonomic nervous system and through it of the glands it controls.

It is our duty to investigate the chronic notion of fear, which we call anxiety, stress, or propossession, in the genesis of cases of hyperthyroidism and also of hyperadrenalism not due directly to morbid action of the adrenal bodies. I have seen cases of Addison's disease in which the only traceable

ætiological factor was prolonged stress, and in which autopsy showed no disease whatever, but merely an atrophy of the adrenal-gland substance. The condition may have been congenital, but the fact remains that prolonged stresses have been shown to exist in each case I have seen. Perhaps these cases are homologues of those where hypoplasia follows hyperactivity of the thyroid gland as described by Wilson. Their prolonged anxiety, demanding much adrenal juice for its pressor effect, would lead to eventual exhaustion of the gland and the hypoplasia found *post mortem* in my cases. In these low-pressure cases, adrenal substance has been beneficial in my hands. But a wise hygiene and more especially a sane psychotherapy are also required to prevent continued exhaustion. Such cases can later remain well without taking adrenal when properly re-educated.

Thus, additional clear, physical intercorrelations of mind and body have been experimentally demonstrated, giving rise to inferences which explain what was formally conceived of so vaguely. From these it will not be difficult to evolve practical means for the relief of suffering and the cure of disease. The scientific psychotherapy which depends on them differs vastly from the crude rule of thumb of the suggestionist. The latter is really no better than the amateur of psychotherapy, whether lay or clerical, who does so much harm with false ideas.

CLINICAL RECORDS.

THE ACUTE SHEDDING OF HAIR IN CERTAIN CIRCULATORY DISORDERS.

By DAVID WALSH, M.D.EDIN.,

Senior Physician, Western Skin Hospital, London.

THE rapid shedding of the hair of the scalp is a subject of which the pathology is still obscure, or, perhaps, one might say with equal justice, is unknown. It is almost invariably connected with some gross failure in the general health, but in some cases it is difficult to say what particular system is at fault. Everyone knows how the hair is apt to fall in cases of diabetes, less rarely in tuberculosis, and commonly in cancer. I have seen a middle-aged woman suffering from extensive cancer *en cuirasse* who could pluck away the hair from her arms at the lightest touch, very much in the way that hair is loosened after exposure to an X-ray tube. Curiously little, by the way, is known as to the destructive action of the focus-tube upon the hair follicles. Nor have we any more definite and satisfactory pathology for the loss of hair in secondary syphilis, but are usually content to refer the phenomenon generally to toxic influences, much as we do in the case of cancer, diabetes and the acute fevers.

In a large number of cases of premature baldness there is evidence of local mischief, such as seborrhoea, to account for the process. Where no such obvious local condition is present, one has to look for explanation in other directions.

There is little doubt that constipation exerts a powerful predisposing or exciting element in the shedding of hair. In this case, however, the toxic theory, pure and simple, fails to cover the whole of the ground. It is easy to understand that the blood may be charged with bowel toxins, but it is not at all clear why they should exert a selective action inimical to the nutrition of the hair-bulb, which, after all, is of an infinitesimally small scale. In approaching this subject it has always seemed to me that in this particular case we were probably attributing to the blood far more power of positive mischief than that to which it was entitled. There

can be little question as to the perverted nutrition of the hair-bulb or hair-root, but may not atrophy have resulted from quantitative rather than from qualitative changes in the blood-supply? In other words, may not the damaged nutrition of the hair follicle and the hair-bulb result from a lessened or interrupted local circulation?

The vicious circle, in my opinion, which is set up in the acute alopecia is somewhat as follows:—The bowel toxins enter the general circulation, where they give rise to anæmia and eventually to the feeble circulation associated with chronic constipation; probably arising ultimately from weakening of the heart muscle. The result is shown in the peripheral circulation and, naturally enough, in the hair follicles and bulbs, which represent some of the finest, if not the finest, capillary endings. The sudden stoppage of nutrition is quickly registered in the dry and shrunken hair-bulb, which is ready to fall out from the follicle with little or no provocation. Or if it be retained for a time by reason of its mechanical interlocking in the upper part of the hair follicle, the failure of nutrition is shown by the changes in the hair-shaft, which becomes dry, brittle and often split at the ends.

The chain of events is probably as follows:—The bowel produces the toxin, which, by reason of stagnation of the bowel contents, is absorbed into the blood-stream; the heart muscle undergoes more or less degeneration, following upon the secondary anæmia and direct and indirect toxic action; the surface circulation suffers, and with it the vascular supply to the hair follicles. The hairs shrivel and fall in consequence. Many acute fevers are attended or, rather, followed, by acute loss of hair. In this sequence of events the primary organ at fault is, in my opinion, probably the heart, the muscle of which has been weakened by the high temperature and by toxic fever products.

The whole subject of the premature loss of hair is ill understood. It has always seemed to me that a common factor is the diminution of the capillary field consequent on undetected failure in the central circulation. This atrophy and disappearance of the surface capillaries is a marked feature in the shrivelled, senile skin. It is shown early in the tight and atrophied scalp, with its accompanying baldness. When these changes, the immobile shrunken scalp and baldness, come on in youth or middle age, I believe they can in most cases be traced to surface atrophy following a temporary or permanent weakness in the central circulation.

The practical deduction is without loss of time to restore the surface circulation and to attend carefully to the state of the heart and general circulation. By means of heart tonics, rest, diet, baths, carefully graduated exercise, a great deal may be done to restore the heart to the adequate performance of its functions. Locally, the use of stimulant lotions and ointments, massage, shampooing, Turkish baths and electrical stimulation are all reasonable and useful measures. Nor must we forget the need of antiseptics to hold local infection in check.

If the explanation of the inadequacy of the heart circulation as the cause of many cases of acute shedding of hair be correct, one would expect to find examples in patients suffering from serious organic disease of the heart. I have noted a connection of the kind in quite a number of cases. Details of three of them are here given:—

Case 1.—C. T., f., æt. 30; school teacher. Hair began falling two years ago; turned grey and broke off short. Five years ago had an attack of gastritis, with severe dyspepsia. Two years ago influenza. Now good health, except constipation and dyspepsia. Mother had rheumatic fever.

Patient has not suffered from rheumatism, but has been subject to sore throats. There is locally on scalp some redness, a few seborrhœic papules and some dandruff, but not enough to account for the loss of hair. The hair is thin, short, fluffy and lustreless. The heart shows mitral regurgitation.

Case 2.—M. B., f., æt. 21, s.; machinist. Complaining of acute loss of hair, which she described as "coming out in handfuls." A fortnight ago the hair was thick, but is now extremely scanty. There is nothing in the scalp to account for the condition. She has twice been laid up with severe rheumatic attacks, one at 8 years (lasting for six months), and another at 18 years (treated in St. George's Hospital). There is aortic obstruction. Pulse 100, good strength. There is some palpitation if excited, but no complaint of shortness of breath, dyspepsia or swelling of ankles. The alopecia was regarded as a delicate clinical sign of failing cutaneous circulation, registered in the hair changes. (From Dr. Meachen's clinic at Blackfriars.)

Case 3.—T. P., f., æt. 28, s.; teacher. Complaining of loss of hair last three years; was previously thick and long, now there is a short, scanty growth. The patient is tremulous and nervous, suffers from dyspepsia and palpitation; feet swell at night. Gets right-sided and frontal headaches. Has mitral stenosis and regurgitation.

Other cases could be added in which patients who have come for advice as to loss of hair have been found to suffer from valvular disease of the heart. In my opinion, as already hinted, we shall one day probably add falling of hair to our early clinical signs of failing compensation.

OPERATING THEATRES.

KING EDWARD'S MEMORIAL HOSPITAL, EALING.

OVARIAN CYST WITH TWISTED PEDICLE.—MR. CARLESS operated on a healthy woman, æt. 30, who, 36 hours before, was wakened from her sleep with acute abdominal pain, which was primarily referred to the left side. This was accompanied by sickness and prostration, which persisted to the next day, when the pain became more marked and shifted to the hypogastric region and to the right rather than to the left side. The temperature was not raised, but the pulse was over 100 and the abdomen somewhat distended; it was not, however, rigid, and there was no abnormal dulness on percussion. Examination per rectum revealed the presence of a rounded swelling in front of the viscus, and on combined vaginal and rectal examination this swelling was more clearly defined as a tense, localised mass about the size of a cocoon and markedly tender. A diagnosis of torsion of an ovarian cyst was made and immediate operation decided on.

The patient having been anaesthetised and placed in the Trendelenburg position, the abdomen was opened in the median line. The first thing met with was an ovarian cyst the size of a large orange, presenting anteriorly and free from rotation or inflammation; this was the right ovary. On passing the hand into the pelvis, the left ovary was found, as anticipated, red and congested with a twisted pedicle in Douglas's pouch. There was a certain amount of free blood-stained fluid in the peritoneal cavity. Both ovaries were removed, the pedicles being transfixed and ligatured with stout silk. The left ovary was twisted on its pedicle three times, and the tube and ovarian tissue were engorged with extravasated blood. There had been so much effusion into the peritoneal cavity that it was thought wise to introduce a Keith's drainage tube for 24 hours; the abdomen was otherwise closed in the usual way.

Mr. Carless pointed out the interesting fact that this

patient's symptoms commenced during sleep, and commented on the frequency with which grave abdominal lesions start in this way. He thought possibly the increased peristalsis resulting from a good supper might have something to do with this, and his own experience pointed to the Sunday night's supper as being frequently responsible for serious attacks of abdominal mischief. Internal strangulation, acute appendicitis, and twists or kinks of an organ are not infrequently produced in this way. In cases of torsion of the viscera, he remarked, one usually finds the viscus twisted on itself two or three times, and it is probable that the trouble had commenced before the final twist is given which determines the strangulation of the viscus. In this particular instance, cross-examination of the patient after operation elicited the fact that she had been complaining of mild abdominal pain for the day or two before the outbreak of serious symptoms. The diagnosis, he said, was made by a consideration jointly of the symptoms and physical signs. The symptoms might have pointed to an internal strangulation under or over a band. Appendicitis was thought of, but ruled out by the absence of fever and of rigidity of the abdominal wall. The localised swelling felt in the pelvis suggested the ovarian origin of the trouble; and he thought too great importance cannot be laid upon the value of a combined rectal and vaginal examination in such conditions. The cysts, when examined, proved to be of the ordinary unilocular variety, and were not dermoids. Ovarian dermoids, Mr. Carless said, are well known to be more prone to rotation than other varieties of ovarian growths.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

MEETING HELD JULY 11TH, 1912.

The President, DR. P. S. ABRAHAM, in the Chair.

DR. TOM ROBINSON showed a man, *æt.* 33, with eczematous dermatitis, who was also the subject of syphilis. Six years ago he had primary and secondary symptoms, followed by punched-out gummata upon the forehead. He had been liable to attacks of an eczematous character every summer.

THE PRESIDENT said he had seen a good many cases of eczema in syphilitics. The combination of syphilis and psoriasis was also not uncommonly met with, but it was, perhaps, a little more puzzling at first sight.

DR. NORMAN MEACHEN showed (1) a case of psoriasis in the sixth generation in a girl, *æt.* 8. The family history was very clear, the transmission being through the paternal grandmother. It was also interesting to note that where there were several children in a generation, the first two would be free from the disease, but the third child would be affected.

(2) Lupus of the ear after piercing for ear-rings. The patient was a married woman, *æt.* 50. The disease affected the lobe and adjacent portion of the right ear, which had been pierced for ear-rings 25 years ago. About six months afterwards a small lump appeared which gradually involved the skin. She had had one X-ray application, and it was proposed to continue this treatment.

THE PRESIDENT showed a boy, *æt.* 9, with canities and leucoderma. About three years ago he had alopecia areata, and the hair turned white upon the patches. Soon afterwards areas of leucoderma appeared upon the hands and feet. The greyness was more marked after an attack of diphtheria. Two years ago he showed signs of left external strabismus, and he began to exhibit curious mental tendencies, among them being an inclination to wander away from home.

DR. ALFRED EDDOWES remarked that in the text books it was stated that leucoderma showed a tendency to be symmetrical. He would go further and say that it was practically always so, and he pointed out the symmetry in the present case.

DR. DAVID WALSH showed a series of coloured drawings to illustrate the connection between

CHRONIC AND RECURRENT SKIN AFFECTIONS AND CARDIAC DISEASE.

Several of these drawings were of chronic or recurrent cases of dermatitis of the limbs of an eczematous or psoriatic type, in which he had found unmistakable evidence of cardiac weakness or actual valvular defects. He maintained that the condition was one of lessened resistance to traumatism due to an enfeebled circulation. In certain cases the eruption would only appear upon failure of compensation, and he considered that this theory might be the key to many an obscure problem in dermatology. Circulatory inadequacy might also be responsible for the failure in certain cases of modern therapeutic methods.

DR. MEACHEN said that he was quite sure that dermatologists often took too narrow a view of their cases. He had been greatly struck not long ago by the fact that several of his cases of an intractable and chronic character were discovered by Dr. Walsh, who kindly examined them one day in his clinic, to have cardiac disease. In one or two instances this fact would easily escape detection unless a systematic examination were made. He thought that a good deal more would be heard of this observation in the near future.

DR. WALSH also showed (1) a young man, *æt.* 22, with alopecia of nervous origin, which had been considerably aggravated by a blow received four months ago.

(2) For Dr. T. P. Beddoes, a case of recurrent universal psoriasis in a man, *æt.* 32. The eruption had appeared regularly every summer since the age of ten, and the father suffered from the same disease.

DR. D. VINRACE showed (1) a man, *æt.* 67, with a fungating condition upon the inner side of the right shin of long duration. A poultice had been applied a year ago to the place, which was then a large reddened patch. No glands were enlarged.

THE PRESIDENT recommended a starch poultice to remove some of the crusts, and afterwards an application of X-rays.

DR. MEACHEN thought that the condition was not infrequently seen upon old-standing eczematous patches upon the legs. The small papillary excrescences were more of the nature of hypertrophied granulation tissue, and it was not necessarily malignant.

(2) A boy with herpes facialis in the right supra-orbital region, which had become infected with impetigo.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, July 20th, 1912.

At the Verein für Innere Medizin und Kinderheilkunde, Hr. Joachimsthal discussed

THE PRESENT POSITION OF THE TREATMENT OF CONGENITAL DISLOCATION OF THE HIP-JOINT.

He said that considering the satisfactory advances made in the treatment of congenital dislocations of the hip during the last twenty years it would be of interest to take a view of the present, and a retrospective glance over it, to also cast a forward glance in respect of the points to be aimed at.

The knowledge that treatment would be the more satisfactory the earlier it could be begun led to a further reconsideration of the diagnostic signs. In this respect he laid special stress on a symptom first brought into notice by himself, by means of which he had invariably recognised the anomaly during the first six months of life. If in a case of unilateral dislocation both thighs were put into a right-angled flexion, and then both were abducted as equally as possible, a difference would be noted between the two thighs. The displacement upwards and backwards would be recognised by a corresponding change of

direction of the thigh, by a distinct "saddling" of the inner surface of the upper part of it, which was made more marked by a springing forward of the adductors, and which could be recognised even when the condition was bilateral.

The treatment in case the age of the patient was suitable consisted in bloodless reposition as carried out by the speaker in nearly 1,000 cases. For the few cases in which the bloody operation was called for to-day the incision in the direction of the adductors as carried out by Ludolph was the proper one. The lower time limit of the bloodless operation was generally accepted to be towards the end of the second year. The speaker had succeeded in determining the luxation in a number of cases within the first six months of life, and in completing the treatment in a comparatively short time. Such early treatment, however, required a special form of bandage. As the higher time limit one should not go beyond the tenth year in unilateral luxations, and not beyond the seventh where the luxation was bilateral. In this way unfortunate accidents were avoided such as fractures, paralyses, etc., but also obstinate stiffenings, etc., that sometimes themselves required treatment later on.

The head of the femur after reduction was generally kept in position by a plaster of Paris bandage covering the pelvis and hips placed in position whilst the thighs were flexed at a right angle and abducted. The children went about with the sole of the foot raised for about three months only in exceptionally strong torsion to be later followed by a second plaster of Paris bandage applied from outwards to within. As the torsion in congenital dislocation of the hip increased with years it was desirable to commence the treatment as early as possible.

If an anatomical reposition had taken place any further mechanical treatment after removal of the bandages was not only superfluous, but injurious. Children regained their normal mobility by their own unaided muscular movements, passive movements might result in recurrence of the luxation. It was only in children approaching the upper age limit, or in such as had been treated very early, that stiffness of the hip affected lasted very long. In the older patients the reason for this lay in the fact that the opposed surfaces of the joint did not fit each other accurately. In the cases of children operated on early, the speaker was of opinion that the lingering stiffness was due to muscular weakness in the infants, who had not power of themselves to stretch the ligaments sufficiently.

Methodical after-examinations, especially by means of the Röntgen rays, had shown that a real return to the normal was possible, and that it actually took place even to the mutual adaptation of the head of the femur and the acetabulum. In contrast to this it had been shown also by material of the speakers, that years after successful reposition, the ends of the femur might become again deformed. Fortunately, however, this result could only be discovered by means of the X-rays; as regarded function the limbs were perfect in the majority of cases. (The speaker here showed a large number of cases, some of which had been under treatment as far back as twelve years, by which it was seen how very satisfactory the treatment of congenital dislocations of the hip had become during comparatively recent years.)

He next showed a case illustrating the healing process in

OSTEOGENESIS IMPERFECTA.

The case was that of a child, aged six months, who came under observation with signs of periosteal dysplasia, with normal epiphysial development, whilst almost all the long bones showed fractures, and were very much flexed. The bones of the skull were like paper, and with the X-rays allowed the convolutions of the brain to be distinctly seen. Although such anomalies were rarely seen except in children that were not viable, in the present instance, by the administration of phosphorus, the child had been kept alive, healing of the fractures had taken place, and to some extent the flexions of the bones had become redressed.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE MANAGERS OF THE EDINBURGH ROYAL INFIRMARY AND THE INSURANCE ACT.

As the result of a conference with members of the honorary staff, the Managers of the Royal Infirmary have adopted an eminently satisfactory attitude in relation to the new position of affairs which has been created by the Insurance Act. It is all the more gratifying that they are making the stand indicated in the resolutions to be referred to, because the Edinburgh Infirmary, historically, and by use and wont, occupies an, in some respects, unique position. It claims, and justly so, to be a national, not a local, institution, and its motto, *palet omnibus*, has, figuratively, blocked the way to all attempts systematically to check abuse of its services by those who are not, strictly speaking, poor persons. It is probably almost the only hospital of the first rank in the kingdom which has never inquired in any way, by almoner or otherwise, into the circumstances of patients. If a man or woman is ill that fact alone secures his treatment within its walls. We are not concerned to defend or to criticise the system; all that we wish to point out is that for a hospital, which since its very foundation worked on these lines, to debar a certain class of persons from its free benefits is the clearest proof that could be afforded of the great change which the Insurance Act foreshadows in the management of voluntary charities. Arising out of the circulation of the complementary pledge various meetings of the staff were held, and it was found that many members of the staff felt themselves precluded from signing the pledge on the ground that to do so might lead them to violate the terms of their service in the Infirmary. Accordingly a deputation met the managers and laid before them a statement of the position in which the medical profession found themselves. After deliberation the managers issued early this week the following sympathetic, and, as we have said, entirely reassuring reply:—"I am directed to say that the Board sympathises with the staff in the difficult position in which they are placed at the present time, but is confident that the staff, while maintaining the fullest loyalty to their professional brethren, will always keep in view the true interests of the sick poor for whom this great charity exists and is supported. I am further directed to say that the Board, after discussion, arrived at the following conclusions:—(1) That in present circumstances insured persons being entitled to medical benefits under the Insurance Act should not be treated in the out-patient department of the hospital except in accident cases, urgent cases, and suitable consultation cases. (2) That the honorary staff shall be entitled to exercise the option (recognised in private practice) to decline to meet any practitioner in consultation should such a course be considered advisable, but always provided that no patient shall be denied immediate advice or treatment if that be requisite on medical grounds. (3) That the question of investigating the circumstances of applicants for the benefits of the hospital by means of almoners or otherwise is one which will require time and care in consideration owing to its undoubted complexity. The managers will, however, give the matter their most careful consideration in due course." The practitioners in the city have received the managers' pronouncement with relief. Determined as they are not to enter into contract practice under the Act, they felt that in a city so full of medical charities as Edinburgh, almost every one of which follows the infirmary's lead of treating all and sundry, their efforts would be rendered nugatory if insured persons could get free medical treatment for the asking. Now this is not to be. The other charitable institutions have not yet decided on their course of action, but there is no real doubt that they will follow the Infirmary, and, even if they did not, there is none which could in any serious way tackle the problem.

NATIONAL INSURANCE ACT SANATORIUM BENEFITS.
—There is not much to chronicle as regards the general trend of events in connection with the Insurance Act, further than to say that the general feeling throughout Scotland is in favour of breaking off what are euphemistically described as "negotiations." Where, as in the present case, we have an organised profession stating their minimum demands, and one of His Majesty's ministers asserting that under no circumstances can these be granted, it is permissible to doubt whether "negotiation," in the ordinary usage of the term, is possible. Dr. McVail, Deputy-Chairman of the Scottish Insurance Commission, addressed the first meeting of the Insurance Committee for the County of Linlithgow, on July 10th, and some of his remarks on the question of sanatorium benefit are not without interest. He explained to the audience the meaning of "sanatorium benefit," and then went on to urge that Insurance Committees should take advice on the subject from medical Officers of Health, and, guided by them, made arrangements for the proper treatment of patients. He then went on to refer to the report of the Departmental Committee, the root idea of whose scheme is a tuberculosis officer, and expressed the hope that the medical profession would bear a share in the work, and would be linked up on suitable terms with the Tuberculosis Officer. The interesting point is that Dr. McVail seems inclined to place the ultimate control of tuberculosis under the Medical Officer of Health rather than under a tuberculosis expert. For ourselves, we should frankly regret this. It is true that tuberculosis is a social as well as a purely clinical problem, but we strongly feel on the side of those who think that the sanatorium benefit, which relates to the actual treatment of tuberculous persons, should be in the hands of, and under the control of clinicians—experts in tuberculosis. The Medical Officers of Health have their hands quite full enough if they deal effectively with, say, the housing problem in connection with tuberculosis, and they really have not the requisite clinical experience to settle how best, in an individual case, sanatorium benefit should be applied. It seems to us that the system that has so long worked successfully in Edinburgh—viz., a separate tuberculosis dispensary and its ramifications, under a clinical expert, is a far more efficient organisation than could have been created by a public health official pure and simple. It is one of the most serious consequences of the ill-considered haste with which the medical benefits of the Act have been conceived that the sanatorium benefits, which in themselves are quite unobjectionable, and ought to prove highly beneficial to the community, stand in danger of suffering through the inability of the medical profession to work them, and may ultimately be thrown into the hands of the public health authorities instead of into the hands of those whose life-long training eminently suits them for such work. Several letters have appeared in the *Scotsman* criticising Sir William Plender's statistics, and one point raised by Dr. A. J. Campbell, Duns, deserves passing mention. He shows that the ratio of doctors to population for the two years is 1 : 2,420 and 1 : 2,838 respectively; that the average of daily visits is 0.33 and 0.01, and points out that in a community of about 2,400 people more than nine patients in a day require visits. In another letter on the subject Dr. Wm. Elder shows that the fees work out at something like 4s. a visit. Clearly, something wrong somewhere.

BELFAST.

THE INSURANCE ACT.—A general meeting of the medical profession in the city was held on Wednesday evening, July 17th, to consider the Act, and was largely attended. The chair was taken by Sir John Byers, who mentioned the various points to come before the meeting for consideration, and emphasised the need of unanimity. A draft letter dealing with the question of contract practice was submitted by the local medical committee, and after some discussion was unanimously adopted and ordered to be printed and circulated among those interested. Briefly, it

lays down the three points approved by the Dublin meeting, and declares that the Belfast practitioners have resolved to adhere to these. The names of those who have signed the declaration will be appended, and it is satisfactory to know that there will be very few of the local practitioners missing. Notice is to be given to the Friendly Societies that the existing contracts will expire at the end of the year, and will only be renewed on the approved terms. A doubt seemed to exist in the minds of some members as to how far these terms are applicable to juvenile societies. It is clear that 8s. 6d. per head is an impossible figure where a number of children in a family belong to a society, and some definite arrangement for families will have to be made. At a meeting of the County Londonderry practitioners held last week, a unanimous agreement was come to as to terms for certificates under the Act, and the pledge issued by the Dublin meeting was cordially approved. If any practitioner in the county is approached by any approved society with the object of securing his services, he should communicate with Dr. Morrison, Blackhill, Coleraine, Co. Derry.

ROYAL VICTORIA HOSPITAL AND THE INSURANCE ACT.
—At the fortnightly meeting of the Board of Management of the Royal Victoria Hospital, Belfast, held last week, the collectors reported that as the result of the Insurance Act some subscribers and firms were withdrawing their subscriptions. The Board decided to send a letter to these subscribers, pointing out that the working of the Insurance Act did not in any way affect the working of the institution or the necessity for funds for carrying on the work, and that, irrespective of the new measure, the demand for beds and calls made upon the hospital would probably increase in the future, or at any rate be on an average with the past.

QUEEN'S UNIVERSITY OF BELFAST.—The annual graduation ceremony of this University was held on July 18th, under the presidency of the Chancellor, the Earl of Shaftesbury, K.C.V.O. The large attendance included many of the members of the Corporation (who wore their robes of office) and representatives of various public bodies. In a brief speech the Chancellor referred to some benefactions recently received, one being the notable gift of £25,000 from the Misses Riddell for the provision of a hall of residence for women students, and another the legacy of £3,000, under the will of the late Mrs. Magrath, widow of Dr. J. Magrath, to found a Magrath clinical scholarship to be given for proficiency in reports of bedside cases, open to fourth year medical students. In the M.D. degree examination, two gold medals were awarded for theses sent in by Dr. Victor Fielden and Dr. Heard. Referring to the former, the Chancellor said that the Professor of Bio-chemistry in the University of Liverpool had expressed the opinion that the thesis would be awarded the highest distinction in any university in this country with whose examinations he was acquainted.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

AUSTRALIA FOR TUBERCULOUS CASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the last few years, I have seen a large number of cases both of early and late phthisis, among immigrants who have come from Great Britain to Australia. These persons allege that they have been advised by doctors to proceed here, as the climate would effect a cure in their cases. Most of these immigrants are lads and young men, and their lot on arrival here is a very unhappy one. They are totally unfit for the hard work of a farm, and they either have to be sent to a consumptive sanatorium or shipped back to England. If what they state about medical advice be true, it is surely very cruel for any medical man to take upon himself the responsibility of sending a patient 12,000 miles from home, where he arrives very

often almost penniless, and where he receives a very scant welcome. If these cases are curable, they can be dealt with much more satisfactorily at home, and if not, it is surely better for them to die surrounded by the care and affection of relatives than amongst indifferent strangers, who resent having this burden cast upon them. I trust that this warning may do something to prevent such cases being sent to Australia.

I am, Sir, yours truly,

RICHARD ARTHUR, M.D. Edin.,

President, Immigration League of Australia.

Sydney.

June 12th, 1912.

THE COST OF THE WASSERMANN TEST.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—We read with very great interest your editorial comment on the cost of the Wassermann test in the current issue of the MEDICAL PRESS AND CIRCULAR. We fully agree with you than many medical men connected with the smaller institutions, and also many general practitioners, find the present price demanded for the Wassermann test prohibitive. In order to meet the wishes of the medical profession generally, the Wassermann Institute has been opened with the express purpose of conducting these tests at the reasonable figure of 15s. In the case of public institutions we allow an appreciable discount. So far as the tests themselves are concerned, these are conducted in strict accordance with the original *technique* and with reagents prepared under the constant control of Professor Wassermann. The Institute is also under the supervision of a medical specialist in venereal diseases. We have long felt that such an Institute was necessary, and we sincerely hope that we may receive the support of the medical profession.

We enclose herewith an announcement card we have this week issued to the medical profession,

We are, Sir, yours truly,

THE WASSERMANN INSTITUTE.

Sutherland House,
Lloyd's Avenue,
London, E.C.
July 18th, 1912.

"UNDER WHICH KING, BEZONIAN? SPEAK OR DIE!"

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Science nowadays advances by leaps and bounds, and it is therefore not perhaps astonishing that a correspondent who signs himself "A Very Simple Practitioner" should show himself hopelessly behind the times, albeit only a few weeks may have elapsed since the epoch-making discovery of the "Great Physical Culturist," about which he writes, has been superseded as the result of more astonishing basic explorations. Your correspondent has evidently never heard of Oxypathy and of the great institution at which this method of curing disease is carried on. This is the message to the suffering world that the Institute of Oxypathy trumpets forth:—

"What would you not give to be for once in your life of faithful labours, REALLY WELL AND STRONG—to feel the rich red blood, the very sap of life, running riot in your veins? BUT—you say: Are all these things possible? YES; OXYPATHY will certainly restore you to health and keep you fit. DRUGS MAY ALLEVIATE BUT CANNOT CURE—NATURE DOES THE CURING—REMEMBER THIS. Your disease is either due to germs or the accumulation of poisonous gases or other matters within the system, or—it may be due to impoverished blood. To retain perfect health you must destroy the germs and eliminate the refuse, or both—you have to make RICH, RED BLOOD. Only one thing has ever been found which is capable of doing this universally and WITHOUT THE LEAST INJURY. This substance is Oxygen." Oxypathy, as might be expected, is of supreme value in "rheumatism, neuralgia, lumbago, sciatica, gout, dyspepsia, asthma, catarrh in all its various forms, constipation, piles, general debility,

neurasthenia, liver troubles, kidney disease and bladder affections, varicose veins, and gall-stones." As to dyspepsia, upon which Dr. Willcox again discourses in your issue this week, in what is called the light of science, but in what is really the darkness of almost mediæval superstition! On the other hand, "OXYPATHY cures completely and permanently any case of dyspepsia, no matter how long the trouble has existed or how complicated it may be. Nervous indigestion, flatulency and loss of appetite are readily overcome. Dyspepsia is generally accompanied by constipation. OXYPATHY will cure chronic constipation. Nearly all persons afflicted with diseases of the digestive organs observe decided improvement after being under treatment only a few days."

If Dr. Willcox is wise he will now give up his hopelessly benighted pronouncements and simplify matters by urging the profession to send their patients to the Institute of Oxypathy. The method employed there evidently represents the last phase in the fairy tale of medical science; it not only supersedes the cumbersome system of what is called orthodox medicine, but even puts in the background the wonderful methods of the "Great Physical Culturist," which up to now so securely held the field.

I am, Sir, yours truly,

AN ASTUTE PRACTITIONER.

Brighton.

July 19th, 1912.

SPECIAL REPORTS.

THE EIGHTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT LIVERPOOL, 1912.

(FROM OUR SPECIAL REPRESENTATIVE.)

It is twenty-nine years since the annual meeting of the British Medical Association was held in Liverpool, and now, upon the occasion of the fourth visit, it is evident that the present meeting will prove to be one of the most successful and largely attended that have ever been held. That it is one of the most momentous gatherings in the whole history of the Association goes without saying, for not only the rights of the medical profession, but also the fate of an Act of Parliament, so to speak, are at stake. Enthusiasm as to the ultimate victory for the profession runs high, and there is little doubt that the resolutions arrived at by the meeting of representatives to break off all negotiations with the Government will be confirmed at the general meeting held to-day (Tuesday). The city is very full, and not a few visitors have found some difficulty in obtaining suitable accommodation.

Sir James Barr, M.D., LL.D., F.R.S.E., the new President, is well known to the profession as a distinguished physician and scientist, in whom the dignity and influence of the Presidentship at this critical time will be well and worthily sustained.

Sir James, who is the eldest son of Samuel Barr, J.P., of Claremont, Tyrone, was educated at Londonderry and Glasgow University, qualifying as M.B. Glas. and L.R.C.S. and L.M. Edin. in 1873, becoming M.D. Glas. in 1882. He was elected F.R.C.P. Lond. in 1902. He received the honour of knighthood in 1905.

In 1906 the University of Toronto honoured him by conferring upon him the degree of LL.D. *honoris causa*, and in 1907 he was chosen the Bradshaw Lecturer at the Royal College of Physicians of London, taking for his subject "The Pleuræ; Pleural Effusion and Its Treatment."

He has always taken the keenest interest in the medical and social life of Liverpool, being Consulting Physician to the Royal Infirmary and Visiting Physician to the Haydock Lodge and Turbrook Asylums. He was formerly Physician to the Stanley and the Northern Hospitals, Liverpool.

Sir James is a Lieut.-Colonel, 1st Western General Hospital, R.A.M.C.

He is also an ex-President of the Lancashire and

Cheshire Branch of the British Medical Association, and also of the Liverpool Medical Institution.

As a writer upon medical subjects Sir James Barr is well known, especially in connection with the circulatory and renal systems.

RELIGIOUS SERVICES.

A Roman Catholic Service will be held at 9 a.m. on Wednesday at the Pro-Cathedral, Copperas Hill, when the celebrant will be Archbishop Whiteside. The Rev. Herbert Lucas, S.J., M.A., will deliver an address.

The Anglican Service will be held at St. Luke's Church, at 2.30 p.m. on Wednesday, when the Bishop of Liverpool (Dr. Chavasse) will preach the sermon.

GENERAL ARRANGEMENTS.

The annual general meeting of the Association was held yesterday afternoon (Tuesday), when the new President was officially inducted. At 8 p.m. Sir James Barr delivered his Presidential address in the Royal Court Theatre, which had been especially reserved for the occasion.

The annual breakfast, organised by the National Temperance League, takes place to-morrow (Thursday), at the Walker Art Gallery, at 8 a.m., when Professor F. W. Mott, M.D., F.R.S., will give an address.

THE WORK OF THE SECTIONS.

The scientific work of the sections, of which there are twenty, commences at ten o'clock this morning. A full and varied programme has been provided for in this direction. In the Section of Medical Sociology, the subject of the formation of a "Public Medical Service under Professional Control" will be sure to draw large audiences. All the sections are commodiously housed in the fine buildings of the University.

THE SOCIAL FUNCTIONS.

To-night a soirée takes place in the Walker Art Gallery. The Local Entertainments Committee has made the most ample provision for the enjoyment of those attending the meeting. To-morrow afternoon a garden party will be given by Dr. C. T. Street at Haydock Lodge Private Asylum, and by Mr. and Mrs. Frank Paul at "The Anchorage," Hoylake. Later on the Lord and Lady Mayoress (Lord and Lady Derby) will give a garden party in the Botanic Gardens.

In the evening the annual dinner of the Association takes place, after which there is to be a performance for ladies of "Mrs. Gorrings Necklace" at the Royal Court Theatre. On Friday, the President and Lady Barr give a garden party at Calderstones Park, and Lord Derby, the Chancellor of the University of Liverpool, will entertain a number of visitors to luncheon at the Town Hall, prior to the conferring of honorary degrees at 2.30 p.m. in the Philharmonic Hall. Sir William Lever will also entertain a party of guests to luncheon at Hulme Hall, Port Sunlight, and he will also entertain a large party to tea in the afternoon and show them over Port Sunlight. Numerous excursions have also been arranged to various outlying country districts.

THE EXHIBITION.

This indispensable feature of the annual meeting, which every member should make a point of visiting at least once, is housed in the Old Gill Street Market, where all the very latest in surgical instruments, drugs, appliances, foods, and medical books are on view daily until Friday (inclusive), from 9 a.m. to 6 p.m.

BUXTON—RE-OPENING OF ST. ANN'S WELL.

In the early days of the present month Buxton was astir with a memorable function—namely, the reconstruction and re-opening of "St. Ann's Well" by His Grace the Duke of Devonshire. Owing to the exceptional interest taken in recent discoveries of the radio-activity of certain waters, excavations were made in the Crescent roadway near the present Thermal Establishment of Buxton, resulting in the discovery of a new source of supply at a temperature of 82° F., of greater radio-activity than the existing sources, and considerably nearer the Pump Room. The new source was found on December 4th of last year, and

at a meeting held on the 8th of that month Mr. Langley, the Town Architect and Surveyor, was instructed to proceed to protect such new supply by the construction of a white glazed chamber built on the rock over the site of the spring. The Well Chamber is 29 ft. long by 14 ft. wide, and elliptical in plan, the floor level being 4 ft. below the general floor of the room.

In the centre of the Well Chamber the chief object—*i.e.*, the well, is placed. It is elliptical in form, the outer shell being formed in cement concrete, lined with blue bricks, and finished inside and out in white statuary marble. Through the perforations in the floor of this basin the waters rise with all their natural properties, overflow the channel, and pass away through a 3 in. waste pipe outlet.

The floors of the Well Chamber and staff room and Chalybeate Room are paved with alternate squares of Swedish green and white Carrara marble; the serving

THE FAMOUS WELL.

landing steps, etc., and wall linings to same are also in white Carrara marble. The back wall of the Well Chamber is faced with fine statuary marble, with two bands of delicate Swedish green marble introduced; altogether a very attractive and artistic effect is produced, surpassing anything we have seen at the thermal establishments on the Continent.

The newly constructed St. Ann's Well, in which the healing water is now dispensed, was the centre of attraction for visitors and townspeople, in addition to those to whom special invitations had been extended. Therein was situate the keynote of Buxton's success, the passport, as it were, to her future increased popularity and prosperity—a never-failing supply of natural thermal mineral water, having distinct radio-active properties, from whose virtues even greater good is hoped for in the treatment of disease than has been the case in the past.

After an inspection of the new Well and the Thermal

Establishment generally by the numerous visitors specially invited, among whom were a large sprinkling of medical authorities from London, the provinces, Ireland and Scotland, an elaborate luncheon was partaken of, at which one toast only was proposed—that of H.M. the King. A procession was then formed and met by the Duke of Devonshire, who remarked on the close connection which had existed for so many generations between members of his family and the town of Buxton, and said how glad he was to have the opportunity of not only renewing but of cementing the ties of affection and regard. It is well known to history that goes back to the time of the Romans that the waters of Buxton have been well and rightly renowned. His only hope was that the fame and name of the town would so continue to increase that even further extensions would be required to meet the growing demands. It is interesting to note here that His Grace is at present undergoing a three-weeks "cure" at Buxton.

Mr. Langley then presented the Duke with a gold key; the door was unlocked, and the holders of tickets flocked into the room. Expressions of surprise and delight came from everybody's lips.

The ceremony of blessing the well was impressively performed by the Vicar of Buxton, the Rev. Canon Scott-Moncrieff, D.D.

Dr. Makower, D.S.C., was then introduced by Mr. W. F. Mill, Chairman of the Urban District Council, and spoke on the radio-activity of the waters, which, he said, must have to some extent been a matter of speculation for some time. Chemical analysis revealed nothing either in the water or gas which would completely explain the marvellous curative properties which the waters were known to possess. Recent experiments had, however, revealed the fact that the waters were of radio-active action, that they contained minute traces of extraordinarily active materials sufficient to produce effects of considerable magnitude. There were minute traces that it would be impossible to detect by ordinary chemical methods, but the waters themselves were known to contain radium emanation, a remarkable gas that was constantly being given off from radium. No doubt that far down below the surface of the ground the water passed over radium deposits and there acquired its activity, an activity which was brought out to the surface of the earth with the gas in solution in the water of the spring. Although the activity had been tested, it must be understood that the quantity of material was very minute, but the quantity compared very favourably with the radio-activity in any source in this country that had been tested. So they had there a comparatively powerful source of supply which might account—though he did not say it was the only factor in the consideration—for the remarkable curative properties of the water.

Speeches followed by Dr. William Ewart, of London, Sir James Barr, of Liverpool, Professor McArdle, of Dublin, and by Dr. A. Shipton on behalf of the local members of the profession.

The formal proceedings then terminated, and from the well the guests proceeded to the baths, then to the Devonshire Hospital, and later to the Pavilion, where tea was provided by the invitation of the Chairman and Directors of the Buxton Gardens Company.

Mr. F. J. C. Broome, the Manager of the Baths and St. Ann's Well, will, we understand, be pleased to show anyone over the whole establishment, and, in addition, to grant free facilities to members of the medical profession to take any of the treatments (over 80 in number).

OBITUARY.

SURGEON-GENERAL S. BLACK ROE.

The death is announced from Ballyconnell, co. Cavan, of Surgeon-General Samuel Black Roe, C.B., in his 82nd year, who had a distinguished military career. Becoming attached to the 92nd Gordon Highlanders in 1855 as Assistant Surgeon, he served with

them until 1882, taking part in the Crimean campaign, and later in the Indian Mutiny, where he was under fire on many occasions. He was also present with the Highlanders in the second Afghan campaign, 1879-1880, and in the Boer war of 1881. After his retirement from the Gordons he was Principal Medical Officer at Madras, a post he held until 1890, when he retired with the rank of Surgeon-General.

DR. W. A. LLOYD-DAVIES, OF WOLVERHAMPTON.

WE regret to announce the death of Dr. William Allan Lloyd-Davies, which took place last week at his residence, "Mountfield," Wolverhampton, aged 47. The deceased, who studied at Owens College, Manchester, and Anderson's College, Glasgow, qualified as L.R.C.P. and S.Edin., L.F.P.S.Glasg., and L.M. in 1892. He held numerous local appointments, and was widely known and respected in the district. He had been suffering for some time past with a weak heart, and a fatal seizure occurred in his consulting-room, all efforts to revive him proving futile.

REVIEWS OF BOOKS.

DICTIONARY OF MEDICAL DIAGNOSIS. (a)

A MEDICAL text-book that has reached a second edition has usually justified its existence and proved its utility, and we congratulate Dr. McKisack on this evidence of the success of his undertaking. This very success, too, absolves us from the necessity of any minute criticism of the work, for since practitioners have been glad to buy the book we may conclude that they have found it valuable. The publication of a second edition has enabled the author to improve the work in many ways, both by the modification of descriptions formerly given and by the addition of new ones. In a work of the kind finality is impossible, for each addition to our knowledge modifies in some respect the value which we attach to the various signs and symptoms presented by our patients. In the methods, too, by which these signs and symptoms are investigated there is a constant change, the older and more complicated giving place to the newer and more simple, and fallacies formerly unsuspected are detected and exposed.

In this edition Dr. McKisack has brought his work well up to the standard of our present knowledge, and placed at the disposal of the practitioner a ready means whereby he may gain information as to the interpretation of the symptoms that he meets in practice, and of the methods he may make use of in the investigation of those signs on the recognition of which accurate diagnosis and successful treatment ultimately rest.

DISEASES OF INFANTS AND CHILDREN. (b)

The second edition of this valuable compendium of Children's Diseases worthily upholds the traditions of its predecessor. All the new and practical advances that have been found to be of service in the field of children's affections have been found a place, and that of vaccines for special diseases has especially been made as practical as our knowledge at present admits, along with those of other recent advances in pædiatrics. The positions held by the authors have enabled them to make full use of their experiences and observations. Each chapter deals with the separate complaints which are likely to be encountered during its existence, and no disorder of any importance has been left untouched. To the practitioner the main value of this book lies in the fact that the authors have discussed at some length the symptoms and causes of disease which fre-

(a) "A Dictionary of Medical Diagnosis. A Treatise on the Signs and Symptoms observed in Diseased Conditions, for the use of Medical Practitioners and Students." By Henry Lawrence McKisack, M.D. Second Edition. 8vo., pp. xi. and 590. London: Bailliere, Tindall and Cox. 1912. Price 10s. 6d. net.

(b) "Diseases of Infants and Children." By H. D. Chapin, M.D., Professor of Diseases of Children, Post-Graduate Medical School and Hospital, and G. R. Pisk, M.D., Adjunct Professor. Second Edition. Pp. 654, with 11 coloured plates and 18 other illustrations. London: Bailliere, Tindall and Cox. 1912. Price 18s. net.

quently are classified as being outside the line of medical disorders. The authors are to be congratulated on their description of *treatment*, which is what the average practitioner reads first, as not being limited in the usual meagre manner; but throughout the book valuable and at the same time practical information is found on nearly every page, more especially that on infant feeding, which enhances the usefulness of the book very considerably. This work on Diseases of Children should be on the bookshelf of every scientific medical practitioner.

ANÆSTHETICS IN DENTAL SURGERY. (a)

IN the elaboration of the means for producing anaesthesia for surgical operations the dental profession has taken a prominent part. Not only were members of that profession leaders in the investigations which made surgical anaesthesia possible, but ever since they have been pioneers in the teaching and perfection of the anaesthetist's art. Both Wells and Morton, to whom, above all others, we owe modern anaesthesia, were practising dentists, and medical men have merely followed the dentists in insisting on a knowledge of the subject as an essential part of the equipment of the members of their profession. Beside this, much of the progress that has been made in the study of the subject has resulted from the co-operation of the doctor and dentist in their endeavours to produce a satisfactory anaesthesia for dental operations.

The book before us is another example of this co-operation, and affords another proof of its value. The authors have clearly and shortly described the various methods they have used and have proved to be satisfactory and useful. A book of the kind depends for its value on the ability of the teachers who have written it, for it is essentially personal in its teaching, but when the writers are teachers of high ability, the value of the book to the student is much greater than any merely impersonal and formal exposition. In the present instance, whether we judge the teachers by their book, or the book by the teachers, the result is extremely satisfactory. The methods recommended are good and the description of them clear and concise. There will, of course, always be differences of opinion between anaesthetists as to which method is the best, but that does not prevent agreement between them as to what is good, and we feel confident that there will be a general agreement in the verdict on those recommended by the authors in this text-book.

In the interesting epitome of the history of surgical anaesthesia, which forms the introduction to the book, we regret to note the omission of any reference to the work of Crawford Long. We are under no obsession as to the position Long occupies in the history of anaesthesia. The world does not owe the great discovery to him, and as far as we can see his work made no difference either to the discovery or the development of anaesthesia, but still there can be no doubt that Long was the first who intentionally induced surgical anaesthesia for surgical purposes by modern methods. Surely he is entitled to be mentioned as much as Wells in any history of the subject. Davy's investigations of the properties of nitrous oxide gas were made in 1800 and not in 1780, as stated in the text.

A NURSE'S LIFE IN WAR AND PEACE. (b)

THE varied experiences of Miss Laurence's life as a nurse in times of war and peace cannot fail to be interesting to all medical readers. Written very naturally and simply, with no straining after effect, the book narrates what may be called just everyday happenings, only that the commonplace is relieved from dullness by being illuminated with the bright tints of enthusiasm and restrained imagination.

Those who were contemporaries with Miss Laurence in the "General Hospital, London," will appreciate

(a) "Anæsthetics in Dental Surgery." By Frank Coleman, M.R.C.S., L.D.S., and Harvey Hilliard, M.R.C.S. With six plates and thirty-eight illustrations in the text. 8vo., pp. x. and 300. London: H. K. Lewis. 1912.

(b) "A Nurse's Life in War and Peace." By E. C. Laurence, R.R.C. With a Preface by Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D. London: Smith, Elder and Co. 1912. Price 5s. net.

the backward glances into "C. Ward" in the early nineties, when the work was so much harder, and the conditions of nursing so widely different from those of the present day. It is not, perhaps, a wildly exciting book, and the narrative is rather disconnected, being written in the form of letters extending over a period of fourteen years; but its charm is found, as Sir Frederick Treves says so aptly in his admirable preface, in its "simplicity, artlessness, and obvious candour."

Miss Laurence has many a tale to tell of the South African War, and her life as an Army sister, which resulted in the fulfilment of her girlish desire to win the Royal Red Cross. Her experiences were full of kaleidoscopic change and unexpected difficulties. Her health, too, gave her trouble at times, but throughout she met all uncomplainingly, and took everything as part of the day's work—a lesson, by the way, worth learning by nurses of the rank and file as well as by the leaders of the profession.

A SYSTEM OF SURGERY. (a)

"A System of Surgery," edited by C. C. Choyce, is composed of three volumes; the first volume, the one now issued, lies before us, and is chiefly devoted to an extensive consideration of Surgical Pathology and General Surgery. In the preparation of this work Dr. Choyce has had the advantage of the co-operation of Professor Beattie, of Sheffield, who is the Pathological Editor, and who has written the sections dealing with the pathological contributions. The greater part of the volume is occupied by an exhaustive study of the pathology of disease, which is treated in its entirety, and no fact of any importance is omitted. There is an extremely good article on spinal analgesia by Dr. Lawrie McGavin, wherein the advantages, indications, and contra-indications, anatomical points, and the phenomena during the effects of analgesia are very ably discussed. Dr. Ironside Bruce contributes an excellent article on X-ray Examination, and the student of tropical medicine will find a clear and lucid contribution from the pen of Dr. C. W. Daniels, of the London Tropical School of Medicine. The book is profusely and clearly illustrated, and the classification adopted throughout reveals the work of an accustomed teacher, and the work of one who is well skilled in the details of a clinical pathological laboratory, and the bacteriological section is equally good. Without exception, all the articles contained in this volume are worthy of most careful study, and the book is singularly free from errors.

CLINICAL DISORDERS OF THE HEART-BEAT. (b)

ALTHOUGH labelled "A Handbook for Practitioners and Students," we doubt whether many of the former will summon up the courage to study the intimate mechanism of heart-block or learn to distinguish between auricular fibrillation and paroxysmal tachycardia. What will interest the general (medical) reader in this monograph are the author's interpretations of sphygmographic readings. In spite of the boldness of these tracings, one is often at a loss to make out their real bearings, and the strokes do not possess the same significance for all observers, be they never so expert. Now the author's conclusions are based on concomitant tracings of the apex beat, so that he is enabled to establish a relationship between the two sets of phenomena and furnish a reason for the faith that is in him.

The author compels our admiration for the elaborate and careful work, thanks to which the physiology—and incidentally the pathology—of the heart-beat has been elucidated and light shed on its most recondite mechanism.

Cardiac pathology possesses great attraction for certain practitioners, and to these Dr. Lewis's book

(a) "A System of Surgery." Edited by O. C. Choyce, M.D., F.R.C.S., Assistant Surgeon Seamen's Hospital, Greenwich, and J. Martin Beattie, M.A., M.D., Professor of Pathology, University of Sheffield. Three volumes. Vol. I. 1912.

(b) "Clinical Disorders of the Heart Beat." By Thomas Lewis, M.D., D.Sc., M.R.C.P., Lecturer in Cardio Pathology, University College Medical School. London: Shaw and Sons. 1912.

will be welcome in that it explains much that was previously obscure.

EUGENICS. (a)

THE story is told that a gentleman of literary tastes once told his friend that he had been to hear an interesting lecture on Keats. The friend replied, "Ah, indeed. By the way, what *are* Keats?" The mental attitude is not unlike that of the ordinary educated man of to-day in regard to eugenics. The word, indeed, is current, but few people take the trouble to understand what it means. For such readers Mr. and Mrs. Whetham have supplied an excellent compendium of information. Sir Francis Galton defined eugenics as "the study of agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally." Assuredly, then, it is not from any lack of importance in its subject-matter that the study has not hitherto received the attention it merits. Nowadays, however, there are signs that this neglect is disappearing. A number of earnest students are devoting themselves whole-heartedly to advancement of knowledge in this direction. Moreover, as we learn from this volume, a Eugenics Education Society has been established, and branches have been formed in various centres. Just here, we think, a certain danger lies. It is quite right that the general public should be led to regard the study of the health of the future race as of primary importance. But the positive knowledge gained is still exiguous, and the danger of inducing amateurs and intellectual dilettanti to affect an interest in any serious branch of study is that they are liable to jump to conclusions without making sure of their premisses. The sympathy of those competent to judge of scientific results is thereby estranged. Indeed, not a few of those who claim to be exponents of the science are in too great a hurry. Even the present volume shows some—not many, we admit—signs of insufficient acquaintance with the fallacies of the methods employed. For instance, discussing (p. 32) the relation between the birth-rate and the death-rate, the authors remark, "A decrease in the death-rate means that more people are living to a greater age, and probably exceeding the limit of years to be assigned to remunerative employment." This is a hasty conclusion, unless one has first made sure that the decreased death-rate is not the result of a decreased birth-rate. An increased birth-rate causes, other things being equal, an increased number of deaths, since the death-rate is highest among children.

Speaking generally, however, Mr. and Mrs. Whetham's book is a sane and well-considered invitation to the study of a very important branch of research. It is, moreover, easy to read, and we can commend it to all who wish to know something of the objects, scope, and methods of eugenics.

HANDBOOK OF MEDICINE. (b)

THIS volume, always a popular one with students, has undergone a process of rejuvenescence which renders it doubly worthy of their esteem. One looks askance at a volume of such modest dimensions (500 pages) professing to cover the whole field of medicine. We have turned over the pages expecting, almost hoping, to discover grave omissions, hopelessly inadequate descriptions, and general "skimpiness." On the contrary, the further one proceeds the more is the reader impressed by the extraordinarily successful way in which even such diffuse, difficult subjects as "fever," "immunity," etc., are clearly set forth in a minimum of space, for, when associated with clearness, brevity greatly facilitates a grasp of the subject.

The work has been brought thoroughly up to date.

(a) "An Introduction to Eugenics." By W. C. D. Whetham, M.A., F.R.S., Fellow and Tutor of Trinity College, Cambridge, and Catherine D. Whetham, his wife. Pp. viii, and 66. Cambridge: Bowers and Bowers. 1912. Price 1s. net.

(b) "Wheeler's Handbook of Medicine." Edited by William B. Jack, B.Sc., M.D., Assistant Physician to the Western Infirmary, Glasgow. Fourth Edition. Edinburgh: E. and S. Livingstone. 1912.

We have data on the therapeutical value of salvarsan, on the scientific use of tuberculin for diagnostic and therapeutical purposes—in fact, all the latest innovations in this department. One little criticism *en passant*. Why does the author discard the use of the customary "sputum" or "expectoration" in favour of the ugly little word "spit." The dictionary defines this word to mean saliva, and this is not what the author intends. Or is the author writing for people who are supposed to be ignorant of the usual technical expressions?

The book is well printed and well presented, and will doubtless be appreciated by those for whom it is primarily intended.

HOW TO BECOME A NURSE. (a)

THAT hardy little annual, Sir Henry Burdett's useful and well-known book, "How to Become a Nurse," blossoms out once more in a new edition, having already appeared in eight previous ones. Besides having undergone careful revision, the new volume contains all the latest regulations and facilities everywhere offered for training, and mentions any additional or special branches lately organised at many institutions, such as massage, midwifery, X-rays, etc.

Widely known as this book already is, we could wish for it a yet larger circulation, so that intending candidates for nursing training might make fewer initial errors in entering the profession. It is not intended for the trained nurse, the preface stating that another volume is soon to be issued at the modest price of 1s., which will deal fully with the object of "How to Succeed as a Trained Nurse," the present one devoting itself entirely to particulars of training schools in the United Kingdom and abroad.

THE SEMI-CIRCULAR CANALS AND SEA-SICKNESS. (b)

AN interesting item of testimony to the persistent survival of the dread ship-sickness, and the recognised importance of the same, is furnished by the publication of the formidable monograph which now lies before us. The writer is evidently an enthusiast; and it is surely from such—we believe, indeed, from such only—that we can reasonably hope to obtain a reliable solution of the sphinx-like problem which has continued to exercise humanity ever since the more venturesome members of its great brotherhood began to go down to the sea in ships. And we can answer for the accuracy of his view of his subject when he suggests that we must look for the key of the mystery among "deeper underlying causes," although "digestive disturbances have always been looked upon by the laity as the primary cause of sea-sickness." In proof of this view he instances the case of the "subject" of one of his extremely careful and exhaustive studies, who sometimes "was dreadfully sea-sick when the stomach, after being irrigated, was presumably in a resting state"; although he "suffered at times from indigestion, and did not at all experience the familiar subjective phenomena of sickness." We may mention as an item of corroborative testimony that one of the most prominent and most healthy of the world's public men in the generation just past was a notedly "bad sailor," a weakness which, we believe, prevented him from ever crossing the Atlantic.

The author has certainly left no stone unturned in the performance of his chosen task of smoothing the pathway to the mystical enclosure which has so long, and so effectively, screened off the mystery of sea-sickness. Of the countless host of anatomical and physiological facts and hypotheses therewith associated, hardly one will be found missing. And his conclusion is that "the true cause," which alone can "afford a reasonable explanation of the phenomena of

(a) "How to become a Nurse." The Nursing Profession: How and Where to Train. Edited by Sir Henry Burdett, K.C.B., K.C.V.O. New and Revised Edition. London: The Scientific Press, Ltd. 1912. Price 2s. net.

(b) "On the Physiology of the Semi-circular Canals and their Relation to Sea-Sickness." By Joseph Byrne, A.M., M.D., LL.B. Pp. ix, and 569. New York: J. T. Dougherty. London: H. K. Lewis. 1912. Price 12s. 6d. net.

most, if not all, of the cases, and of the mode of their production . . . is to be found in functional labyrinthine disturbances, due directly to the boat's motions. . . ." The idea is, of course, not absolutely new. It was, we believe, originally suggested by the anatomical disposition in osseous space of the curiously disposed semi-circular canals themselves. These are so eminently suggestive of the Cartesian planes and co-ordinates which yield to the mathematician all the data requisite to the location of a point, and the prophetic measurement of all its relations in space! For the treatment—it is, we are disposed to think, but fair to the author to suggest to the reader that he should consult the volume for himself. But we may mention that in cases "where the psychic factor predominates . . . hypnosis is of undoubted benefit." The assertion that "hyoscin should never be used in sea-sickness" recalls the case of an "eminent" consulting physician who began a hyoscin campaign against neuroses after reading the evidence in the Crippen case—he had not known the virtues of that alkaloid before! And we conclude our notice of this carefully prepared monograph with an offering of cordial thanks to the author for the vast amount of information here concentrated for our benefit.

SYSTEMATIC CASE-TAKING FOR MEDICAL STUDENTS. (a)

ON the care and thoroughness with which the student carries out his training in case-taking depends the success or otherwise of his medical career. Medicine, we have been told, is essentially a matter of observation, and case-taking is an object lesson in the art of observing.

The field of observation has been greatly extended of late, so much so that the busy practitioner must perforce relegate much research work to specialists in that department; nevertheless he must know of and about these methods, or he will not be able to avail himself of the information to be obtained thereby, and not to be cognisant of their value nowadays is to be quite "out of the running."

The author in the space at his disposal gives a good *aperçu* of the various steps in the clinical examination and briefly summarises the supplementary means of investigation. The student will find this work of great assistance in the wards, and even to the busy practitioner it constitutes a useful work of reference.

HEREDITY. (b)

THE subject of heredity is now very much in the public eye, and very necessarily so, having regard to the increasing acuteness of the racial and individual struggle for existence; and to the increasing scare of race suicide, the expanding gospel of eugenics, and the demand for measures preventive of the survival of the unfit. The science of the past half-century has swept away many of the old landmarks of the former pedagogic progress, real or fancied, of view-points regarding the phenomena and laws of organic life. The importance of the great question of heredity has been always recognised in the twilight stages of the collective intelligence of human communities. It has also received a peculiar significance of characteristically modern flavour since the date of the promulgation of the theory of evolution. The author opens his lecture by pointing out the very remarkably contrasted feature of the teaching of the pathology of the present day, compared with that of former years: "the gradual recession and disuse of the word 'diathesis' as the true microbic cause of disease after disease became unravelled." This leads him to the denial of any share to heredity in the causation of tuberculosis.

(a) "Systematic Case Taking for Medical Students." By H. L. McKisack, M.D., M.R.C.P., Physician to the Royal Victoria Hospital, Belfast. London: Bailliere, Tindall and Cox, 1912. Price 3s. 6d. net.

(b) "The Bradshaw Lecture on some Points in Heredity." Delivered before the Royal College of Surgeons of England on December 6th, 1911. By R. Clement Lucas, B.S., M.B.Lond., F.R.C.S. Pp. 50. London: Adlard and Son, 1912.

Still, he exhibits broad views on the influence of heredity in other directions. For instance: "The liability to the production of twins can, I think, be shown to be hereditary." We think so, too. And he has no hesitation in suggesting the great desirability of intercepting the very undesirable reproduction of "tainted stocks" by judicious utilisation of the benefit of the discovery that "exposure to the X-rays destroys the reproductive function of the generative organs without injury to the individual." Weismannism and Mendelism are sufficiently discussed, and judiciously—sometimes severely—criticised. Many other view-points and illustrative positions are introduced to the reader, who must find the lecture highly suggestive, even if he cannot always subscribe to the author's somewhat dogmatic statements.

LITERARY NOTES.

THE fourth edition of "Anæsthetics and their Administration," by Sir Frederic W. Hewitt, M.V.O., will be published in September by Messrs. Macmillan and Co. In the preparation of the new edition of this standard work, which has been thoroughly revised and brought up to date, the author has been assisted by Dr. Henry Robinson, Anæsthetist to the Samaritan Hospital and to the Cancer Hospital.

* * *

We welcome, though a little tardily, the appearance of *The Review of Bacteriology, Protozoology and General Parasitology*, as an independent publication. This abstract formerly appeared as a supplement to the *Medical Officer*, and had gained the confidence of all workers in the subjects with which it deals. It will in future appear five or six times a year, at an annual subscription of half-a-guinea. Single copies will not be sold. The editors are Mr. Alexander Foulerton and Dr. Charles Slater, who are assisted by a competent staff.

* * *

THE current number of "Pearson's Magazine" deals most opportunely with the dangers to health arising from the common house fly. Nothing could be more convincing to the popular mind than the photographic illustrations depicting the transference of disease germs, carried by the fly's legs, from putrid material and refuse to the mouth of a baby. The opinions of many well-known scientists are epitomised in a few telling phrases, headed by the letters "F.M.G.," which, being interpreted, mean "flies must go!" The value of the educative articles like this in the popular magazines cannot be over-estimated as serving to spread the principles of hygiene among the masses. Copies of the descriptive leaflet with which the article closes may be obtained for public distribution at cheap rates upon application to the Editor of "Pearson's Magazine."

* * *

THE first number of the "Zentral-Organ der Medizin," which is an international monthly bibliographical review, has made its appearance, edited by H. Albert-Hellmers, of Hamburg. The new periodical consists of only two essential parts, the first being a list of all the more important current contributions to the whole of medical literature arranged in alphabetical order as a subject-index, the second portion being merely an index of authors. It will be seen, therefore, that this review is compiled upon a much simpler plan than that of the "Index Medicus," for if the author's name be known, it is an easy matter to turn this up and to find against it a reference number which is attached to his particular paper or papers that it is desired to trace. This number is next found in the first part, where the title of the paper and full details of the journal in which it appeared are given. There are no sub-divisions into departments of medical science in the first list, a fact which, though tending to simplification, renders it essential that only the most important word in the title of a paper whereby it may readily be identified should be indexed. Thus, it is of little use to index the article, "Influence of Salts upon the Action of Rennet on Milk," under the

word "Influence," unless it were understood that the first important word of an article should always be indexed, but this is not the universal rule. Names of new books recently published also appear in the list which, if minor inconsistencies are eliminated, will prove to be a most valuable publication.

MEDICAL NEWS IN BRIEF.

A Central Health Committee for London.

AFTER consultation with the Local Government Board, a Committee representing the Central Voluntary Health Associations summoned a conference, which was held at the Mansion House last week, to consider the desirability of forming a Central Health Committee for London which would promote joint action between metropolitan municipal authorities and voluntary health agencies in the prevention of disease and in the education of all classes in matters of health and domestic hygiene. Sir Melville Beachcroft presided.

The Chairman said the difficulty lay in the plethora of bodies which were dealing with the same subject, and it was now desirable to co-ordinate all these agencies.

Dr. F. J. Allan (Mansion House Council on Health and Housing) proposed the first resolution, which declared that it was desirable that a Central Health Committee for London should be formed.

Sir John Tweedie (National League for Physical Education and Improvement) seconded, and it was eventually carried *nem. con.*

Professor Kenwood (Vice-Chairman of the National Health Society) proposed, Dr. Prudence Gaffikin (Women's Imperial Health Association) seconded, and Mr. H. P. Boulnois supported, a resolution that the following authorities and voluntary agencies be invited to appoint representatives upon the Committee, which should have power to add to its number:—Local Government Board, Board of Education, London County Council, Metropolitan Asylums Board, Association of Medical Officers of Health (Metropolitan Branch), Jewish Board of Guardians, London Biblewomen and Nurses' Mission or Ranyard Nurses, Mansion House Council on Health and Housing, National League for Physical Education and Improvement, National Health Society, National Bureau for Promoting General Welfare of the Deaf, Federation of Metropolitan District Nursing Associations (Queen Victoria's Jubilee Institute of Nurses), Royal Sanitary Institute, Women's Imperial Health Association, and the Social Welfare Association for London.

This was carried, and it was resolved, on the motion of Dr. Murray Leslie (chairman of the Women's Imperial Health Association), seconded by Mr. A. J. Martin (Vice-Chairman of the National Health Week Committee), that the Social Welfare Association for London be requested to take steps to give effect to the resolutions and that the Local Government Board be asked to allow the Committee to meet at the offices of the Department.

King's College Hospital.

THE Committee for the removal of King's College Hospital to South London have just received a cheque for £20,000, being the balance of the gift of £50,000 recently made to the fund by an anonymous donor. By the donor's desire, £4,000 of the total donation is allotted to the sum required for the building of the Medical School in connection with the new hospital.

Croydon Hospital Extension.

THE new wing of Croydon Hospital, which has been erected from designs of Mr. Frank Windsor as a memorial to King Edward VII., was opened on Saturday last by the Mayor of Croydon, Alderman Trumble. The new wing provides an isolation department, a ward with 18 cots, bedrooms for nurses, kitchen accommodation, and improvements. Extensions have also been made to the Royal Alfred wing of the hos-

pital. The total cost is £5,500, of which £4,000 has been raised by public subscription. The dedication service was conducted by the Bishop of Croydon, assisted by Canon White-Thomson. Sir Frederick Edridge, Chairman of the Committee, announced that he had received an offer of £1,000 to be paid when the remainder of the balance required had been promised. The Mayor stated that £250 of the amount had been promised during the afternoon.

Medical Report on Osborne.

THE report of the House Governor and Medical Superintendent at Osborne for the year ended March 31st last was issued last week. The total admissions numbered 315, of whom 59 were ladies. There was a marked increase in the number of officers treated. It is pointed out that it is not easy to explain the fluctuating admission rate. The Naval and Military medical statistics for 1911 have not yet been published, so that any comparison of the general sick rate of the year under review with previous years is not yet possible. It is noted, however, that the increase has been spread over all branches of the Services both at home and abroad. On the whole the patients benefited much by their residence at Osborne, and their state on discharge is shown as follows:—Recovered, 184; improved, 34; no change, 3; died, 1; and remained in Home on March 31st, 34; total, 256.

The Colonial Office Medical Staff.

WE understand that Sir Patrick Manson, M.D., F.R.S., will retire from the post of Medical Adviser to the Colonial Office on August 15th, and that he will be succeeded, on the appointment of the Secretary for the Colonies, by Sir J. Rose Bradford, M.D., F.R.S., as Senior Medical Adviser, and by Dr. C. W. Daniels, M.B., M.R.C.P., as Junior Medical Adviser. These appointments will take effect from the date of Sir Patrick Manson's retirement. Mr. W. T. Prout, M.B., late Principal Medical Officer, Sierra Leone, is to be Medical Adviser to the Colonial Office in Liverpool. The King has been pleased to give directions for the appointment of Sir Patrick Manson to be a Knight Grand Cross of the Order of St. Michael and St. George, in recognition of his eminent services in connection with the investigation of the cause and cure of tropical disease.

Holiday Lectures and Drill.

THE National League for Physical Education and Improvement is organising a summer school at The Cloisters, Letchworth, during August. There will be theoretical lectures on physical education, health, eugenics, and kindred subjects, and daily practical classes in Swedish drill, peasant dances and games, old English country and Morris dances, swimming, tennis, and many other forms of outdoor exercise and recreation. Each course will last a fortnight, and particulars may be obtained from Miss T. Johnson, The Swedish Institute, Clifton, Bristol.

The Royal Sanitary Institute.

THE Royal Sanitary Institute Preliminary Programme of the twenty-seventh Congress, to be held in York from July 29th to August 3rd, has now been issued. H.R.H. Prince Arthur of Connaught, K.G., will open the Health Exhibition on Saturday, June 27th, at 3 p.m., and special services have been arranged in the Cathedral and other churches on the Sunday. Professor Karl Pearson, M.A., LL.B., F.R.S., will deliver the Lecture to the Congress on "Eugenics and the Public Health." Professor Henry R. Kenwood, M.B., D.P.H., F.R.S.E., will deliver the Popular Lecture on "The Healthy Home." Excursions to places of interest in connection with Sanitation, a *Concursazione*, Garden Parties, and other entertainments have been arranged for those attending the Congress. More than 350 authorities, including Foreign and Colonial Governments, Government Departments, County Councils, County Boroughs, other Sanitary Authorities, Universities and Societies have already appointed delegates to the Congress; and, as there are over 4,000 Members and Associates in the Institute, a large

attendance is expected. In connection with the Congress, a Health Exhibition of Apparatus and Appliances relating to Health and Domestic use will be held in the Exhibition Buildings, as practical illustration of the appliances and carrying out of the principles and methods discussed at the meetings; it not only serves this purpose, but also an important one in diffusing sanitary knowledge. The local arrangements are in the hands of an influential Local Committee, presided over by the Rt. Hon. the Lord Mayor (Ald. Norman Green), with the Town Clerk (H. Craven), the Medical Officer of Health (E. M. Smith, M.D., D.P.H.), and the City Engineer (F. W. Spurr) as Local Hon. Secretaries.

The following have been elected members of the Institute:—Hugh E. Finch, M.B.Oxon, D.P.H.Lond., District Health Officer, Christchurch, New Zealand; Robert H. Makgill, M.D.Edin., D.P.H.Camb., District Health Officer, Auckland, New Zealand; and Emile Nadeau, M.D., Quebec Immigration Hospital, Quebec, Canada.

Medical Attendance in the Highlands.

It is officially announced that the Chancellor of the Exchequer has appointed a Committee to consider how far the provision of medical attendance in the Highlands and Islands of Scotland is inadequate, and to advise as to the best method of securing a satisfactory medical service therein, regard being had to the duties and responsibilities of the several public authorities operating in such districts. The Committee will consist of the following:—Sir John Dewar, Bart., M.P. for Invernesshire (Chairman); the Marquis of Tullibardine, Mr. J. Cullen Grierson, Convener for the County of Zetland; Mr. Andrew Lindsay, Convener for the County of Sutherland; Dr. Leslie Mackenzie, Medical Member of the Local Government Board for Scotland; Dr. J. C. M'Vail, Deputy-Chairman of the Scottish Insurance Commission; Dr. A. C. Miller, Medical Officer for the parishes of Kilmallie and Kilmonivaig; Mr. Charles Orrock, Chamberlain of the Lews; Mr. J. L. Robertson, LL.D., Senior Chief Inspector of Schools for Scotland. The Secretary of the Committee will be Mr. M. Beaton, one of the inspectors under the Scottish Insurance Commission.

A Tuberculosis Dispensary for Hampstead.

The Hampstead Borough Council at its meeting last week decided to establish a tuberculosis dispensary and sanctioned the expenditure of £750 per annum for its maintenance. It is suggested that the dispensary should be housed in the projected Health Institute, which is to be the memorial to the late King Edward.

The Peamount Sanatorium Wrecked.

FIFTY men, armed with pickaxes and other implements, on Sunday evening last attacked the new sanatorium at Peamount, Co. Dublin, which is being built by the Women's National Health Association, and practically demolished it. Their action is attributed to the hostility of the residents to the establishment of a tuberculosis sanatorium in their locality.

Report of Dublin Prevention Committee on Infantile Mortality.

THE Dublin Committee, in its report for the first half of the second year since its inception, states that 80 ladies are at present working as voluntary health visitors under its auspices; 30 others have been trained during the winter, and are now ready to take up this work. Nine hundred mothers and their babies have been visited since last January; 10,800 visits have been paid during that period, 775 bags of coal have been distributed, 400 articles of clothing given to mothers, and 6,585 milk or food certificates have been issued. Under the Early Notification of Births Act, the Public Health Department of the Corporation inform the Secretary of the Committee when and where a birth takes place in the city. The Secretary forwards the name and address to the health visitor, who visits the mother and baby once every ten days till the child is twelve months old. The visitor is supplied with a certain number of milk and coal tickets, which she distributes

in necessitous cases. Sewing classes have been established in several parishes, where the visitors instruct poor women how to make babies' clothes. As the work is only starting, the Committee does not feel justified in appealing to mortality returns, so as to institute comparisons for this last year as against previous ones. Its work is principally of an educative character, diffusing knowledge and help in the homes of the very poor.

University of London.

THE following have passed the M.D. Examination for Internal and External students:—

Medicine.—S. H. Booth, B.S., Univ. of Leeds; H. C. R. Darling, B.S., and H. S. Furness, B.S., Univ. Coll. Hosp.; Rose F. Jordan, B.S., London (R.F.H.) Sch. of Med. for Women; T. S. Lukis, B.S. (University Medal), St. Bartholomew's; E. G. Perodeau, B.S., and C. E. Shattock, B.S., Univ. Coll. Hosp.; N. Tattersall, B.S., Manchester Univ.; H. A. Treadgold, B.S., Camb. and King's Coll. Hosp.; H. O. West, B.S., King's Coll. Hosp.; S. Wyard, B.S., Univ. Coll., Cardiff, and Univ. Coll. Hosp.

Mental Diseases and Psychology.—B. Hart, Univ. Coll. Hosp.; G. E. Peachell, B.S., St. Mary's.

Midwifery and Diseases of Women.—H. L. Barker, B.S., St. Mary's; R. L. E. Downer, B.S., St. Bartholomew's; H. B. Foster, Guy's; G. B. Harland, B.S., Univ. of Durham; G. Macted, B.S. (University Medal), Guy's.

State Medicine.—W. A. Daley, B.S., B.Sc., and W. Scarisbrick, B.S., B.Sc., Univ. of Liverpool.

Tropical Medicine.—Ardeshir Koyaji Contractor, B.S., London Sch. of Trop. Med. and Univ. Coll. Hosp.; F. C. McCombie, King's Coll. Hosp. and London Sch. of Trop. Med.; Dossibai Rustomji C. Patell, B.S., London Sch. of Trop. Med.; and R. O. Sibley, St. Mary's.

University of Oxford.

THE following candidates have satisfied the examiners for the Diploma in Public Health:—

Part II.—W. F. Rhodes and W. D. Watson.
Parts I. and II.—L. E. Acomb, W. A. Berry, F. G. Caley, H. K. Fry, and J. P. Johnson.

Part I.—Ram Swarup Agrawal, R. Donald, Kalka Prasad Mather, and A. H. Tebbutt.

University of Cambridge.

AT a Congregation held on July 11th the following degrees were conferred:—

M.B. and B.C.—A. M. Bodkin, King's; J. S. Burn, J. W. H. Chunn, and M. Donaldson, Trinity; J. R. Marrack and C. H. G. Philp, St. John's; E. Rayner, Pembroke; R. Ellis, Cath.

M.B.—W. Broughton-Alcock, Trin. Hall.
B.C.—J. W. Dew, Clare; W. L. Johnson, Pembroke; C. B. Wainwright and J. L. McI. Weeks, Caius; H. F. Wilson and C. R. Wright, Christ's; J. M. Jarvie, Emmanuel; A. E. Bonny and W. J. Fison, Sidney; E. F. W. Grellier, Downing.

University of Bristol.

AT the third examination for the degree of B.D.S. during the present month, Mr. Reginald H. Basker secured a pass; and Mr. Alfred W. Adams and Mr. Frank K. Hayman passed the second examination for the degree of B.D.S.

Examination for the Degree of M.D.—Pass with honours, John W. Taylor.

Final Examination for the Degrees of M.B., Ch.B.—Pass: Alfred G. T. Fisher, Henry W. Goodden, Chas. H. Hart, Vivian St. Leger Pinnock. Part I, only: P. Emil Christofferson and Claude Kingston.

Examination for the Diploma in Public Health.—Part I, only: Thomas Aubrey, Sidney Bazalgette, Alexander H. Finch and Wallace Pomeroy.

Society of Apothecaries of London.

THE following candidates having passed the necessary examinations, have been awarded the L.S.A., entitling them to practise Medicine, Surgery and Midwifery:—A. E. Bullock, L. M. Ladell and A. J. Tozer.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DR. J. DONALD (Lisard).—The product, "Colloid co per," referred to by Dr. de Gers, in his lecture (MEDICAL PRESS, July 3rd) on "Decancerisation," is little known in this country, although commonly used in France. The only chemists at which we have been able to learn it is stocked in London are Messrs. Wilcox, Jozeau and Co., Haymarket.

DR. P. N. R. (Hants).—Of the localised forms of hyperidrosis, the axillary and inguinal are, according to Dr. Belot, the most amenable to treatment by X-rays, the most appropriate dose being 4H units at a distance of about 35cm.

MEDICAL MISSION WORK IN UGANDA.

ACCORDING to the last report the Mengo Medical Mission Hospital in Uganda, under the control of the Church Missionary Society has relieved an immense amount of physical suffering. No needy case is ever refused; the hospital doors stand open day and night. During the year the buildings of the hospital have been added to, the equipment of the wards and operating-rooms has been greatly improved, and a special hospital has been built for Europeans. The number of in-patients received into the hospital and its dispensaries during the year was 2,081, and there were 72,445 attendances of out-patients. Some 25,000 prescriptions were dispensed, and over seven tons of medicines and dressings were used.

DR. M. S. (Warwick).—The subject is fully dealt with in "The Treasury of Human Inheritance," Parts I. and II., issued by the Galton Laboratory, price 14s. net.

MORPHIA AND COCAINE IN INDIA.

SPEAKING in the House of Commons last week, Mr. Montagu, in reply to Sir J. D. Rees, said "With a view to control the use of morphia and cocaine in India, their importation by post is altogether prohibited, and their importation by other means is severely restricted, and is limited to persons holding permits issued by prescribed authorities. The manufacture of morphia from illicit opium by private persons is prohibited, and the amount of morphia which a private person may possess is limited. Transport from place to place is carefully regulated, as is also sale, both wholesale and retail. As regards cocaine, its sale is restricted to chemists and druggists holding licences, and sale by them to private persons must be for bona-fide medicinal purposes and on the prescription of a qualified medical practitioner."

M.D. (Bristol).—The diagnosis of whether or not a growth is of a malignant type can be determined by a blood examination after the Shaw-Mackenzie method.

EXCELSIOR.—The latest reports of the vaccine treatment of enteric fever in India indicate a firm belief in its efficacy among those having personal knowledge of its results. Confirmation of this belief is shown in the fact that in the United States army the inoculations are now compulsory.

Appointments.

BRADFORD, Sir J. ROSE, K.C.M.G., F.R.S., Senior Medical Adviser to the Colonial Office.

BROOK, T. STANBURY, M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Chingford Urban District Council.

CLIFFORD, W., L.R.C.S.Irel., L.K.Q.C.P.Irel., Certifying Surgeon under the Factory and Workshop Acts for the Adare District of the county of Limerick.

DANIELS, C. W., M.B.Cantab., M.R.C.P.Lond., Junior Medical Adviser to the Colonial Office.

GELLE, ERNEST S., M.B., B.S.Durh., House Surgeon to the Italian Hospital, Queen Square, W.C.

LEISHMAN, A., L.F.P.S.Glasg., Assistant Medical Officer to the Teesdale Board of Guardians.

REECE, RICHARD, M.D.Cantab., D.P.H., Assistant Medical Officer to the Local Government Board.

SHAW, A., M.D.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the St. Austell District of the county of Cornwall.

Vacancies.

Down County Council.—Medical Superintendent. Salary £500 per annum, with an allowance of £150 per annum, for travelling expenses. Applications to the Secretary, Council Offices, Courthouse, Downpatrick.

London County Asylum, Colney Hatch, New Southgate, N.—Junior Assistant Medical Officer. Salary £170 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums' Committee, Asylums' Committee Office, 6 Waterloo Place, S.W.

Stockport Union.—Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary £130 per annum, with furnished apartments, rations, etc. Applications to Charles F. Johnson, Clerk to the Guardians, Union Offices, Shaw Heath, Stockport.

Gravesend Hospital.—House Surgeon. Salary £100 per annum, with board, and residence. Applications to W. Pearson, Secretary.

Hereford County and City Asylum.—Assistant Medical Officer. Salary £170 per annum, with board, lodging, washing, etc. Applications to Medical Superintendent, Asylum, Burghill, Hereford.

Macclesfield General Infirmary.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Chairman of the House Committee.

Liverpool Dispensaries.—Head Surgeon. Salary £170 per annum, with board and apartments. Applications to the Secretary, 56 Vauxhall Road, Liverpool.

Queen Mary's Hospital for Children, Carshalton, Surrey.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Board, Embankment, London, E.C.

Staffordshire County Asylum.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.

Brixton Dispensary, Water Lane, S.W.—Resident Medical Officer. Salary £175 per annum, with furnished apartments, attendance, coal, and gas. Applications to W. Halliday, Secretary.

Staffordshire General Infirmary, Stafford.—House Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to Richard Battle, Secretary, Stafford.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to E. Burton, Hon. Secretary.

University of Birmingham.—Lecturer in Physiological Department. Salary £200 per annum. Applications to Geo. H. Morley, Secretary.

Carnarvonshire and Anglesey Infirmary, Bangor.—House Surgeon. Salary £100 per annum, with board, washing, and lodging in the house. Applications to the Hon. Secretary.

Nottingham General Dispensary.—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 High Pavement, Nottingham.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to Neville Holden, Hon. Secretary.

Births.

CRIMP.—On July 16th, at Brackenhurst, Walton-on-Thames, the wife of G. L. Crimp, M.B., B.C., B.A. (Cantab.), of a son. Both doing well.

POOLEY.—On July 20th, at 15 Gladstone Road, Ranmoor, Sheffield, the wife of G. H. Pooley, F.R.C.S., of a son.

Marriages.

BULLOCK—PHILLIPS.—On July 10th, at Holy Trinity Church, Maitland, Nova Scotia, William Bullock, of Port Colborne, Ontario, only son of the late Frederick William Bullock, of Halifax, and grandson of the Very Revd. William Bullock, first Dean of Nova Scotia, to Norah Stuart, only daughter of Stephen Thos. Phillips, L.R.C.P., etc., of Maitland, N.S., late of Wellington, Hereford.

Deaths.

ABRAHAMS.—On July 22nd, at 14 Welbeck Street, W., Jane, widow of Dr. B. L. Abrahams, and dearly beloved daughter of A. J. Simmons.

LLOYD-DAVIES.—On July 16th, at Wolverhampton, William Allan Lloyd-Davies, L.R.C.P. and S.Edin., L.F.P.S.Glasg., aged 47.

DOCTOR'S RESIDENCE,

Gordon Square, London, W.C.—To be let, one of the best houses in this favourite square; seven bedrooms, four excellent reception-rooms, and commodious offices.—Particulars of Messrs. Edwin Fox, Bousfield, Burnetts, and Baddley, 99 Gresham Street, City.

THE MEDICAL PRESS AND CIRCULAR

No. 5.

NOTES AND COMMENTS.

Quality Before Quantity. DURING the week that is past much has been heard of the various problems connected with race culture, especially with regard to the part played by the medical profession in raising the physical and mental standard of generations yet unborn. Public interest has already been aroused in the new science of eugenics, while the subject has been brought in a practical way before the notice of medical men and scientists in general at the first international Eugenics Congress, which began its sittings last week at the University of London under the presidency of Major Leonard Darwin. That a more conscious selection must replace the blind forces of natural selection has long been the ardent desire of those who yearn for the improvement of posterity. It certainly stands to reason that some check must be placed upon the propagation of the race by those who are morally and physically degenerate. The maintenance of a high birth-rate, unless associated with a strong progeny, is not necessarily an indication of the upward progress of a nation. As we have been reminded in the Presidential Address before the annual meeting of the British Medical Association, held at Liverpool last week, we must "breed for intelligence." It is quality that tells ultimately in the building up of a sound and healthy race, not merely quantity at any price. It is largely in the hands of the medical profession to point out the paths along which the moral, intellectual and physical evolution of the race can be accomplished.

Temperance Workers and Drink Philanthropists. ONE of the not least interesting functions of the Liverpool meeting was the Annual Temperance Breakfast in the Walker Art Gallery. After a substantial meal at 8 a.m., a large gathering was entertained by speeches which had the merit of brevity, in view of the sectional meetings which began at 10. The chairman, Mr. A. Guthrie, is a well-known local temperance worker. He alluded to the fact that in Liverpool no less than 800 licences had been extinguished, and that before the passage of recent legislation that town had for many years excluded children from the public-houses by virtue of a special Act. In his practical address, Dr. Mott claimed that the tolerance of the temperance party in the Association could not have been better demonstrated than by their readiness to meet in a public building founded by the munificence of a great local brewer and distiller. In spite of the adage which warns us against looking a gift horse in the mouth, it is nevertheless a matter of regret that some medical charities should in some cases derive vast sums of money from the drink traffic, from money-lending, from stock exchange speculation, company pro-

moting, and other more or less immoral sources of wealth.

The Preponderance of Female Population. THE 36,070,492 persons enumerated in England and Wales show an excess of 1,179,276 females over males. These figures want some correction as regards the males engaged in the Services abroad. The solid fact remains, however, that since the year 1821 the female preponderance has, on the whole, steadily increased. Where is all this to end—or is it even desirable, in the best future interests of society, that women should not get the upper hand? Why should not man, who has hitherto been the dominant sex, gracefully resign that position in favour of his womenfolk? It would be well, perhaps, to bring about the change with some amount of deliberation, inasmuch as the world's physical fighting appears to be by no means at an end—that is to say, if we may judge from the vast and increasing amount spent upon armaments by nations in all parts of the world. Be that as it may, if we wish to readjust the sex balance it may be done without any undue tax upon the resources of civilisation by calling in the aid of medical science. The great initial fact with which we are faced is that, so far as the actual births are concerned, the male sex is predominant—but boy babies die off more rapidly than girl babies.

Why Boy Babies Die. A COLLECTIVE medical inquiry into the causes of the excess in male infantile mortality might yield important practical results. The explanation that used to be given in the text-books was that the male infant was larger than the female both in head and in body, and consequently was liable to greater injury during parturition. If that alone were the essential determining condition of the excess, it might be remedied without undue strain upon the resources even of the hybrid midwife to whom has been entrusted the duty of superintending the entry of our offspring into the world. But the whole of the male excess is not accounted for in infancy, for the women are more resistant after middle age. It is worthy of note that the feminine excess was most marked in Surrey, Middlesex, London and the Isle of Wight. It seems a pity that these women should be unable to follow the men who have freely migrated to the Colonies. It is worthy of note that the proportion of prison population was only 139 females to 1,000 males, even after allowing for the Suffrage Movement. In only one European country—Norway—did the female preponderance exceed that of our own country.

An Epileptic Homicide.

A WEEK or two ago we commented on the fact that a man had been found naked in a London street early one morning, brandishing an axe, wherewith he seriously assaulted a constable. At the time it was suggested in these columns that the prisoner's actions were of such a nature as *prima facie* to suggest the absolute necessity of an inquiry into the state of his mind. For once in a way the police authorities have done the right thing, and a medical investigation showed that the man suffered from epileptic fits, and at times did not know what he was doing. The magistrate, Alderman Burnett, thereupon dismissed the charge and gave the prisoner's mother a letter for a suitable hospital. We may point out that to hand over a homicidal epileptic to the care of a hospital is to court future disaster. A hospital is unfitted to deal with such a patient, and we suggest the proper method would have been to secure a proper investigation by competent alienists, with a view, if necessary, to detention in Broadmoor. If this man ranges the streets again with an axe the result may be a tragedy for which the police would be morally responsible. What medical man versed in insanity would have sanctioned such a step?

An Indian Medical Service For Women.

THE question of the position of medical women in India has been before the India Office and the Government of India for some time past. It has been felt that the problem of medical aid for the female population of India would be met, to a great extent, by the establishment of training schools for native women. The deputation which waited recently upon the Secretary of State for India were of the opinion that a central administrative body in India (which need not involve the disruption of the Dufferin Fund) should be created for the purpose of managing the women's medical department, and for the establishment of teaching hospitals, efficiently staffed, where Indian women graduates could receive adequate training in midwifery and diseases of women and children. It is not, we gather, the intention of those best informed with regard to Indian social conditions, to run such a service on exactly the same lines as the Indian Medical Service, for it is well known that the tendency of the Indian Government is in the direction of encouraging private practitioners rather than for the provision of medical aid for the general population as a State affair.

LEADING ARTICLES.

NATIONAL INSURANCE ACT NEGOTIATIONS AT AN END!

THE eightieth annual meeting of the British Medical Association, which concluded its session at Liverpool last week, must be regarded as the most momentous ever held within the annals of the Association. The main fact stands out with startling prominence, that in the report stage of the annual representative meeting it was determined by an overwhelming majority to break off negotiations with the Chancellor of the Exchequer on the question of medical benefits, except on terms already laid down, and to call on all medical men to refuse or resign appointments under the Act. The only exception permitted was in regard to sanatorium benefit, "provided it is carried out in accordance with the wishes of the Association, until

such time as the Government has satisfied the Association that its demands will be met." This weighty decision must fall upon the medical profession with the force of finality that necessarily attends any profound resolution, whether affecting a nation or a large section of the community. It marks the end of negotiations that medical men have felt all along were conducted on the side of the Government in a spirit of political juggling rather than of plain, straightforward dealing. Only a few days before the Liverpool meeting, after the Act had come into operation, a restricted actuarial inquiry was conducted into medical incomes. A more grotesque placing of the cart before the horse it would be difficult to imagine. In spite of his great political abilities and experience, it seems fairly obvious that Mr. Lloyd George has fallen into grave errors in his attempt to cajole the medical profession into playing the part of catspaw for the vicarious philanthropy of the Liberal party. In the early stages he ignored the profession altogether, and then fell into the error of regarding it as synonymous with the British Medical Association. As to the latter body, he apparently thought that by securing the Council he secured the members, but the outcry at the appointment of the Association Medical Secretary, Mr. Smith Whitaker, to the Insurance Commissioners must have come as a somewhat rude awakening from those beliefs. As the outcome of this curious string of transactions, the British Medical Association has become in fact the spokesman of a profession that is practically united for the purpose of collective defence. It has become more and more apparent for the past six months that Mr. Lloyd George, in spite of much show of friendship and conciliation, has made no concession of any material value to the medical profession. The *Daily News*, to which we turn as an official Liberal organ, has reflected the official view with candour throughout every stage of the Insurance legislation. At first that estimable journal scouted the "doctors' revolt," and treated their protests with sarcasm of fine Fleet Street flavour. Later it became somewhat alarmed, and handed over the subject to "P. W. W.," a political writer of ability, but, as a rule, narrow and ill-informed in outside social matters. Lately it has entrusted one of its best writers, Mr. Harold Spender, to deal with the doctors, but he can hardly be said to have thrown much light upon the discussion. Another suggestive fact is that it has lately turned for an article to Dr. Addison, M.P., who, rightly or wrongly, has been regarded by many medical men as answerable for a good deal of the Chancellor's misinformation as to the inner conditions and feeling of the medical profession. All along the *Daily News* has insisted that medical men have been actuated by political motives. So often and so industriously has this absurd statement been circulated that the challenge has been accepted by THE MEDICAL PRESS AND CIRCULAR, and we have deliberately advised medical men, regardless of their individual polit-

views, to oppose tooth and nail at the next Parliamentary election the Government which has so unjustly violated their private interests. The aggregate political weight of the medical profession is enormous, and he must indeed be a bold Minister who would face an issue of that kind. Meanwhile, the point now before the medical profession is the speedy organisation of a public medical service, the control of which will be in their own hands. The Chancellor of the Exchequer is not a weak man, neither does he allow grass to grow under his feet, and his next move in the matter is hardly likely to be long delayed. His characteristic obstinacy of character has been shown in the recent negotiations, and it now remains to be seen what will be the outcome of his struggle with a thoroughly aroused profession. It would be interesting to speculate what his attitude would be were Parliament to force contract service upon the lawyers; but law is just as necessary as medicine if the average poor citizen is to enjoy to the full the blessings of life in a civilised community. That which is politically just for medical men can hardly be wrong for the lawyers, even though it be possibly less expedient for a strenuous Cabinet Minister. Meanwhile, it looks very much like a declaration of war to the knife.

THE INFLUENCES MODIFYING THE CIRCULATION.

ONE result of modern physiological research has been to show the intimate relations that exist between the various systems of the body, more especially with regard to the circulatory mechanism. The whole of the vascular system may be profoundly influenced, for instance, as the result of disturbances of secretion of one or other of the group of mysterious organs known as the ductless glands. Recent research has materially increased our knowledge of the functions of these bodies, and practical therapeutics has considerably gained thereby. We have only to contrast the present-day treatment of such affections as Graves's disease, myxœdema, and Addisonism with that of the period when the active principles of the secretions of the ductless glands were unknown. In the address in medicine delivered at the annual meeting of the British Medical Association last week, a full abstract of which appears in our columns, Dr. G. A. Gibson dealt with this subject in a masterly fashion, showing most conclusively that the "chemical messenger" or hormone contained in these secretions is able to influence glandular activity, and through it the circulatory mechanism, in a specific manner. These powerful agents appear to act upon many, perhaps all, tissues, some by affecting the local processes of repair and removal, others by acting directly upon the muscular wall of the blood vessels, and others, again, through the medium of the sympathetic and vaso-motor nervous systems. Thus, the effect of the administration of suprarenal extract upon the blood vessels is to cause marked constriction, except in those of the heart and lungs, while pituitary extract contains at least two sub-

stances, one of which causes contraction and the other dilatation. The secretion of the thyroid gland is capable of being influenced by sudden shocks, such as a severe fright, symptoms of exophthalmic goitre supervening, perhaps, in the course of a few hours. It has also been ascertained more recently that profound nervous influences may produce definite changes in the suprarenal secretion. The nervous and glandular systems would appear, therefore, to be intimately correlated with the vascular mechanism, and both clinical observation and experimental research strengthen the hypothesis that the somewhat obscure diseases under consideration have a dual or even a triple origin. That they may be due, directly, to circulatory disturbances appears probable on superficial examination, but if we trace the ætiology further back still, the primary cause will be found to reside in some defect in the glandular or nervous control over the heart and blood vessels themselves. As our pharmacological knowledge of the active principles of the ductless glands advances, there is reason to believe that many diseased conditions will become more amenable to treatment. A greater devotion to the three sister studies of physiology, pathology, and pharmacology must result, as Dr. Gibson has pointed out, in a practical advance in the therapeutics of disease.

CURRENT TOPICS.

The Eugenic Ideal.

THE opening last week of the First International Eugenic Congress marks the deep interest of scientists, philosophers, and statesmen alike in the youngest of the ancillary sciences of medicine. Even the public, or, at any rate, the more enlightened section thereof, are beginning to realise what it means to live for posterity, and to understand that, for the future of the race, it is as important to breed from sound stock in the case of human beings as it is for the domestic animals. Some of the more complex of eugenic problems were touched upon in the admirable speech delivered by Mr. Balfour at the international banquet of the Congress at the Hotel Cecil, who said that the whole point of eugenics was that it rejected mere numbers. The Lord Mayor of London, with his keen professional insight, rightly stated, in proposing the toast of "The Eugenic Ideal," that the problem of the greatest social importance was the inculcation of the responsibilities of marriage among the youth of the present day. Eugenics must be taught in the cottage as well as in the lecture-hall. Indeed, the tactful persuasion and influence of medical practitioners, clergymen, teachers, and health-visitors will do much to instil higher ideals of marriage with special reference to the future progeny, while at the same time they can popularise a greater study of the laws of heredity among the masses. The public must be convinced by every possible means that the acquisition of this knowledge is one of the most pressing necessities of the age.

Alcohol and Disease.

ONE of the most significant facts of modern therapeutics and social economics is the changed attitude of the medical profession concerning the use of alcohol in disease. Regarded merely as a beverage in health there will always remain differences of opinion, but there can be no doubt whatever that alcohol does not hold the same place in the pharmacopœia as it once did. Hospital staffs no longer order the daily quantities of beer, wine, or spirits to their patients that were customary a generation ago. In fact, with the general wave of temperance that has undoubtedly swept over the country, owing to changed habits on the part of the people, has come a reluctance to employ a substance the administration of which was felt to carry with it certain risks. It is interesting, therefore, to note that at the recent breakfast held at Liverpool last week under the auspices of the National Temperance League, the two principal medical speakers, Sir James Barr and Professor F. W. Mott, were neither of them total abstainers. Both recognised fully that too much alcohol was consumed at the present day, but both acknowledged that a great advance had been made in the direction of temperance. Both, again, stated that they did not order alcohol in disease except in small quantities, or in exceptional cases. Such testimony from unbiassed practising physicians is in itself a striking confirmation of modern experimental research into the action of alcohol upon the physical and mental economy. It seems likely, therefore, that the administration of alcohol in sickness will be yet more scientifically conducted in the future, having due regard to its limitations and drawbacks.

Hospital Efficiency.

IT is not improbable that in the course of the next few years the attention of the public will be turned much more to hospital administration and efficiency than it has been in the past. Discussion of medical benefits under any scheme of National Insurance must embrace careful consideration of hospital management. In America there is a widespread feeling that hospital machinery has a large coefficient of waste energy, and this the leaders in medicine are using all their powers to reduce. The opening address at the Surgical Section of the American Medical Association held last month dealt with the hospital problem, a fact which shows how important this subject is considered. The view is put forward that the only place for the surgically ill is hospital, and that not a nursing home, but a general hospital, on the same plan as our large charity hospitals. Some of the leading American surgeons will not operate unless the patient comes to the general hospital, and the latter contains a large number of private rooms. This procedure is not only more convenient for the busy surgeon, as it saves the time usually occupied in going to the private hospitals or the patient's home, but it is also of advantage to the patient in that he is nursed by a staff familiar with the surgeon's methods, and in a place possessing, as a rule, more facilities for

emergencies than the ordinary nursing home. Moreover, for the purposes of clinical research and statistical inquiry, it is much more convenient to have all one's patients in the same institution. Moreover, the fees received from private patients would be of considerable service in the general upkeep of the hospital. It is more economical to maintain one large hospital than a large number of small, and often inefficient, institutions. Another point which is under discussion at present has to do with the allocation of cases to the various members of the staff. The Massachusetts General Hospital has adopted the plan of giving all the cases of cancer of the uterus to one surgeon, those of biliary disease to another, and so on, each surgeon restricting himself to a special branch for a certain time. By this means each surgeon gets much more practice in any given line of work than he could possibly obtain by the older method, and as a result becomes more efficient therein. There are, of course, arguments against both these suggestions, but it is always well to know how problems are dealt with elsewhere.

The Sanatorium Benefit.

IT is a matter of importance, both to the public and the profession, that the representative meeting of the British Medical Association has expressed itself as not hostile to the administration of the sanatorium benefit, "provided it is carried on in accordance with the wishes of the Association." There is now no obstacle on the part of the medical profession to the satisfactory working of this benefit, which can be made of great service in the public health work of the country. There are, however, certain anomalies in the position taken by the British Medical Association. While permitting its members to accept offices for the administration of the benefit, it has ordered their withdrawal from all provisional insurance committees, that is to say, from the committees who have to make all arrangements for the administration of the benefit. It is obvious that the arrangements are less likely to be satisfactory if medical men have no share in making them. In the hurry of business at the meeting this point and some others seem to have been overlooked. We hope that the Council may find some way out of the difficulty, as otherwise policies and schemes for the sanatorium benefit may be put into operation without proper advice.

Vacation Schools.

THE custom has been growing of late years of attending classes or courses of instruction in some special subject in what is usually regarded as holiday time. Primarily the movement was started in order to give school-teachers and senior students an opportunity of acquiring special knowledge, practical or otherwise, in some branch of learning in which they were interested, or in which they desired to become more proficient. Frequently such courses are combined with pleasure excursions, something after the manner of the annual meeting of the British Medical Association, for instance, and, thus, little by little, the movement has grown to such an extent that quite a large percentage of the com-

munity combines instruction with recreation during the yearly holiday. It may well be asked whether, on medical grounds, such a union of work and play is strictly advisable, or if, indeed, it may not defeat its own ends. The answer is to be found, we think, in the mental and physical attitude of the individual who attends such a vacation course. The whole essence of a healthful holiday is that it should be as much unlike the ordinary routine as possible, so that the tired mental worker will not, physiologically, derive so much benefit from his brief period of change if it consist even in part of teaching or listening to lectures. Such may well be advised to stay away, while others who have not been subjected to severe strain of this kind may derive considerable benefit from attending a vacation school. Anything like mental or physical over-exertion when on a holiday should be strenuously avoided.

Sanitation in India.

It is announced that further steps are about to be taken for improving and strengthening the sanitary service in India. At present the schemes include a greater decentralisation of control, and a widening of the field of recruitment by throwing open the higher posts to fully qualified Indians of proved aptitude. The local Governments are to be empowered to select their own sanitary commissioners from officers serving in provincial sanitary departments, under certain limitations as to previous sanction. The existing number of deputy sanitary commissioners is inadequate in more than one province, the area served by one of these officers in Madras being more than 129,000 square miles with a population of 36½ millions. It has been decided to create eight additional appointments of this class. The deputy sanitary commissionerships will no longer be reserved for officers of the Indian Medical Service, and Indians possessing the necessary qualifications will be eligible. The candidate must hold a British diploma in public health and be a properly qualified medical practitioner. Health officers of the first class are also to be appointed for the larger municipalities and of the second class for the smaller towns, to supplement the work of the district Civil surgeons, who, as a rule, are the only health officers of the towns of their respective districts. A health officer of the first class must have a registrable medical qualification and a British diploma in public health. It is hoped that it may be possible to remove the second restriction so soon as arrangements can be made in India which will enable Indians trained there to become health officers of the first class.

PERSONAL.

H.M. QUEEN ALEXANDRA, accompanied by H.M. Queen Amelie of Portugal, paid a visit last week to the Lord Mayor Treloar Cripples' Hospital and College.

H.M. QUEEN AMELIE visited the Royal Free Hospital last week, inspecting the wards of the institution.

MR. H. TYRELL GRAY, F.R.C.S., has been appointed an Assistant Surgeon to the West London Hospital.

MR. OSWALD L. ADDISON, F.R.C.S., has been appointed an Assistant Surgeon to the West London Hospital.

MR. SYDNEY GRAY MACDONALD, F.R.C.S., has been appointed Surgical Registrar to the West London Hospital.

DR. SEYMOUR TAYLOR, M.D., F.R.C.P., has been appointed Consulting Physician to the West London Hospital.

MR. F. SWINFORD EDWARDS, F.R.C.S., has been appointed Consulting Surgeon to the West London Hospital.

MR. W. S. EDMOND, F.R.C.S., has been appointed Surgeon to the X-ray Department of the Salop Infirmary.

DR. LLEWELLYN WILLIAMS, of Wrexham, has been appointed Medical Inspector to the Welsh Insurance Commission.

MR. F. E. SCRASE, F.R.C.S., D.P.H., has been appointed Medical Officer of Health for the Borough of Hampstead.

MR. DONALD ARMOUR, M.B., M.R.C.P.Lond., F.R.C.S., has been appointed Surgeon to the West London Hospital.

MR. HAROLD LEADER, M.B., M.R.C.S., L.R.C.P., has been appointed Lecturer in Diseases of Children in the University of Sheffield.

DR. A. J. W. STEPHEN, M.B., Ch.B., D.P.H., has been appointed Medical Officer of Health to the Weetslade Urban District Council.

SIR WILLIAM THORNLEY STOKER, Bart., M.D., late of Dublin, who died on June 1st, aged 67, left personal estate in the United Kingdom valued at £10,315.

MR. SIDNEY ARTHUR BOYD, M.S.Lond., F.R.C.S., has been appointed Surgeon to Out-patients at the Hampstead General and North-West London Hospital.

DR. F. WOOD-JONES, M.B., D.Sc.Lond., has been appointed Lecturer and head of the Department of Anatomy at the London (Royal Free Hospital) School of Medicine for Women.

SIR DAVID FERRIER, M.D., F.R.S., has been awarded the Moxon Gold Medal of the Royal College of Physicians of London, given triennially for distinguished research in clinical medicine.

MR. W. NETHERVILLE BARRON, M.V.O., M.R.C.S., now Surgeon Apothecary to their Royal Highnesses Prince and Princess Christian of Schleswig-Holstein, has been appointed to be their Physician in Ordinary.

A CLINICAL LECTURE

ON

THE TREATMENT OF DECUBITUS.

By ALEXANDER ZWEIG, M.D.,

Physician to the City Asylum, Dalldorf, Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IN the year 1884, my chief, Herr Geheimrath Sander, at the suggestion of Bruns, as a new method of bedding for cases of paralysis with uncleanness, introduced prepared wood wool into the asylum, and after some months' experience with it made a report on it in the *Berliner Klinischen Wochenschrift*. Up to now we have kept to the wood wool uninterruptedly, and this fact alone shows that this method of treatment has maintained its ground. Wood wool is used in some institutions, but it always seems to be so little known that it is deserving of a fresh word of praise. It struck me that the large numbers of both foreign and native physicians who visited the institution last year, and who passed wonderingly through the wards, looked upon the use of wood wool as a "new method." In our female infirm wards there are on an average 24 untidy more or less weak-minded patients. Last year it happened that in two instances only were we unable to get a case of decubitus to heal up; one of the two patients was at the same time suffering from renal disease (chronic nephritis), the other from diabetes; complications the injurious action of which on the tissues is well known. With these results the special methods employed along with the wood wool must be of interest.

We procure the wood wool, as before, from the firm of Paul Hartmann, Heidenheim a.B., Würtemberg. It is prepared from the aspen (*populus tremula*), which is cut up on some specially prepared cutting machines. The shavings are then cleaned and deprived of their ammonia, then put through an antisepticising process, impregnated with sublimate, and lastly reduced to the form of elastic wood wool in special machines. They are employed in the manner described by Sander, so that I cannot do better than make use of his own words: "The patient is placed on the wood wool without any other material, without linen, india-rubber, or any other material. To this end, the floor of the bed not being pierced through, the sides of it are slightly raised, the wood wool is lightly spread about 7 inches deep, an ordinary cushion is supplied for the head, the patient placed in bed and covered up. It is to be noted that the wood wool is not placed in a bag as filling for a mattress, and that the bedclothes are omitted. I have decided to omit even the shirt, as it so often gets into the folds and creases and gives the first impetus to pressure gangrene. The material in which the patient lies is agreeably cool, soft, 'giving,' and elastic. It clings to the contours of the body so closely that after a time a true impression of the outlines of the back is given off as with a plaster cast. The urine is soaked up by the wood wool, and as far as this gets moist it is removed with a small shovel. The faecal matter is treated in a similar way." The wood wool is teased out and softened and stirred up every day, and that which is used up is replaced by fresh.

The advantages of wood wool, without any further remarks, are sufficiently clear. Every practitioner knows how difficult it is to handle a large

water bed and how easily, even with the greatest care, folds are formed in the lower part of the bedclothes, the enormous amount of washing demanded when patients are soiled, etc. As Sander had pointed out, wood wool is useful not only in preventing the advance of a decubitus already formed, but it has an active curative effect. In accordance with this view, patients who are seriously ill have submitted to the wood wool treatment quite independently of its uses as a cleanser, and very gratifying results have been obtained. Last year, in some specially severe cases, I have supported the action of the wood wool by special treatment of the decubitus. The soft bedding impregnated with sublimate has simply the aim of protecting the body from pressure, of soaking up the moisture, thus protecting the skin from its injurious effects, removal of suppuration in a quick and easy manner, all these things are, of course, of great moment. Besides this the patients had a cleansing bath every day, and parts that seem in danger are rubbed with vinegar water (one tablespoonful of officinal dilute acetic acid to 1 litre of water). This is done every time there is any soiling. The camphor wine formerly in use is much dearer, and it is in no way better than the acetic acid.

Simply by the use of these means decubitus was warded off in many cases. If any redness was noticed, a warm camomile bath was given once or twice a day; when the patient was unable to sit up a sitz bath was given instead. Although "bath camomile" was not the kind employed but an inferior kind of "camomile" tea, the cost of such a bath was within moderate bounds. The duration of a bath varied according to the degree of redness, the general condition of the patient, and the heart, and was kept up as long as possible. I might say here that in severe cases I made daily use of the bath with advantage for a week together, the patient being kept in the bath as long as possible.

If, in spite of such measures, there was any loss of substance or the period of redness was overlooked, zinc ointment was rubbed into the affected part, but without any dressing. In this way we succeeded in all cases in decubitus appearing during the patient's stay in the hospital—*i.e.*, in all initial stages.

In all other severe cases—in all patients coming in with decubitus—I have used with good effect:—

R Arg. nit., 1.0;
Bals. Peru, 20.0;
Vasellini ad 100.0.

This ointment is spread on to a thin layer of gauze and placed all over and around the decubitus and renewed daily. The gauze is then covered with a layer of lint and fastened with sticking plaster. The plaster made use of is Remmler's "Collem" adhesive plaster. Irritations of the skin, in spite of prolonged use, were never observed. On every removal of the plaster all shreds of adhering plaster were carefully removed. Even in these cases also treatment by sitz camomile baths was all that was needed. I should say here that in spite of the concentration of the Peruvian balsam no effect on the kidneys was ever noticed. But, considering the

situation of the different places, very little could have become absorbed. On the other hand, caution should be observed in the use of the ointment, especially as regards the skin near the edges of the decubitus. In order to protect these parts from the Peru balsam, they should be first covered with zinc ointment.

The treatment becomes still more energetic when necrosis is present. Here all shreds of necrosed tissue are carefully removed with the scissors, frequently the floor of the ulcer is curetted as well as the lateral parts. By choice the patient is then put directly into the camomile bath and kept there the whole day. Here the permanent bath arrangements were important, especially as regarded the regulation of the temperature. I did not arrange for a constant outflow in view of the waste of camomile. By this method of use we were able to give an eight-hours' camomile bath for about three pence. As these patients were mostly marantic, they were given as a precautionary measure strophanthus; no collapse was ever observed. For various reasons the removal of the necrotic shreds is advisable. In the first place they prevent applications reaching the still living tissues, and diminish their usefulness; further, the removal diminishes the secretions, and through each of these factors shortens the period of active treatment. The curetting also effects a lively flow of blood through the healthy tissues bordering on the necrosis. The contents of skin pockets I sometimes succeeded in cleaning by peroxyd spray, when the froth arising was allowed to remain for some time. If after two or three days no effect was produced by this, the skin covering the pockets was cut through at once. At first I strove against this method of treatment, as I could not bring myself to enlarge the so-slowly healing wound. But you would be surprised how quickly everything healed after radical removal of all dead tissues with a possibility of healthy secretions and free entrance to all remedial agents. In the period between the bath and the night the arg. nit.-Peruvian balsam ointment was applied in the manner above described to the parts affected.

There were, it is true, also cases in which this treatment failed to act, where in the morning the ulcer was full of secretion and dead products. Here the sound cleared the matter up. If the whole of the border round the ulcer was carefully explored, you would be surprised to find the sound suddenly sink into a depth of some centimetres, whilst the skin above appeared to be completely intact. In one case I could follow the ulcer from the prominent part of the sacrum up to the commencement of the lumbar vertebræ. Sometimes we find several such passages. Tamponade with the most varied material, iodoform gauze, peroxyd of hydrogen, gauze steeped in sublimate, with arg. nit.-Peruvian balsam ointment, powder of arg. nit. (arg. nit. Bal. alb. equal parts) had no effect. It was but with a heavy heart that I at last decided to split up the whole track on the grooved sound. The result as it was with the skin pockets was surprisingly good, and in such cases since then I have split up these passages at once, regardless of their length, and always with a prompt result. When there are several such passages the slitting of the longest is generally sufficient. More lately in every case of decubitus I have examined with the sound most carefully, and strongly recommend the precautionary measure. Many non-healing bedsores are cleared up by this procedure.

I should here not omit to mention one disadvantage in wood wool, already pointed out by Sander, noticeable especially when nurses are rather rough or patients impatiently restless, and that is the not inconsiderable quantity of dust. In spite of every

care, and when every precaution has been taken, this cannot be altogether prevented. Generally speaking, this should not prevent the use of the wood wool, as during the years it has been in use with us there has been no case of injury to the mucous surfaces either on the part of patients or nurses, and the manufacturers of the material, in answer to a question put to them, said that some of the workpeople had been employed on the same work for tens of years and without the least injury to health. Matters are quite different, however, in cases of infectious diseases of the intestines. Here the possibility must be considered that the bacilli of the disease may be spread through the dust on to food, and one must consider that the bacilli of typhoid are very resistant to drying. These considerations led us last year in the face of a small epidemic to the use of peat moss in place of wood wool. This substance is also for many reasons very suitable as bedding for unclean patients. In my opinion, however, apart from such times, wood wool is the more suitable of the two. Moreover, the firm make also wood wool lint tissue and gauze, which are less dusty than the wood wool itself. But I have no experience with the latter-named articles.

On the other hand, it would be unjust to condemn its use in epidemics of typhoid without mentioning that it possibly has advantages in combating such a disease when used as a vehicle for conveying away infectious evacuations. Sanders has already pointed this out. It is not to be doubted that the soaking up of diarrhœic stools will be a hindrance to the spread of such diseases. The impregnating with sublimate will also play a part. It speaks for a favourable action on the part of wood wool that in earlier years some epidemics of typhoid appeared in the female division of the infirmary, that the disease, in spite of the large number of marantic individuals, was limited to one ward, and that, according to the reports, no great harm resulted from the outbreak, and that it was easily suppressed. As regards these points, it was possible that the exchange of moss for wood wool made it more difficult to come to a determination. Perhaps a bacteriological investigation as to the employment of wood wool in infectious diseases of the intestines would clear up the point.

Conclusions.—From a prophylactic point of view, it is important to place cases of decubitus in wood wool, that it must be regularly kept clean and soft; further, the parts must be washed daily with vinegar and water, and, for therapeutical purposes, camomile baths must be made use of along with zinc ointment. In severe cases the parts must be treated with an ointment of silver nitrate and Peruvian balsam, the necrotic parts must be steadily taken away, and passages as steadily opened up. Examination with the sound is specially important. In this way, apart from other tissue changes, every bed sore may be made to heal up in a comparatively short time.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by M. Castaigne, M.D., Professor at the Faculty of Medicine of Paris; Physician to the Beaujon Hospital. Subject: "Digestive Uræmia Simulating Cancer of the Pylorus."

THE Council of the Royal College of Surgeons has decided to place a bust of the late Lord Lister in the College, and to ask Sir Thomas Brock, R.A., to undertake the execution of the work.

ORIGINAL PAPERS.

THE FUTURE OF THE MEDICAL PROFESSION. (a)

BY SIR JAMES BARR, M.D., LL.D., F.R.S.E.,
Consulting Physician, Liverpool Royal Infirmary.

LADIES AND GENTLEMEN,—When I was considering what subject I should choose for my presidential address, I chanced to read the Huxley lecture on Life and Consciousness by Henri Bergson. He there asks the questions: "What are we? What are we doing here? Whence do we come and whither do we go?" Without following Bergson's philosophic disquisition as to how life and consciousness permeate matter, and as to how they were started on their evolutionary career by an original impetus, it occurred to me that these questions might be very appropriately asked of the medical profession. What are we? Can we show any sufficient *raison d'être* for our existence? Are we of sufficient value to individuals and to the State to justify our continued existence as a profession? Is the world any happier for our presence? Are we really an advantage to the higher evolution of the race? Natural evolution, and the evolution of the art and science of medicine run on different lines; they are often mutually opposed except when Nature gets the upper hand, and medical men are blindly following their ideas of natural laws. Nature is lavish in the production of life and prodigal in its destruction; her efforts are directed to the improvement and perfection of the species, she cares nothing for the individuals except to adapt them to the environment. This process of adaptation spells elimination for the unfit, and thus we get the survival of those best suited for their surroundings, and these in their turn produce a vigorous, intellectual, and self-reliant race. Medicine, on the other hand, has been evolved for the benefit of individuals. It does not deal with the unborn, but merely devotes attention to the living. We not infrequently hear such exclamations as "What has posterity done for us? Why should we consider the future of the race? It is sufficient for us to look after our own progeny who have already arrived in this world." It seems sufficient for a good many people to know that they have descended from William the Conqueror, or from some of his mighty men of valour whose virile power they have not yet quite succeeded in dissipating. They are not very particular as to the purity of the germ-plasm which they are handing on to succeeding generations.

MEDICINE AND RACE-CULTURE.

Medical men are ever more or less successfully adapting the environment to the individual, and giving the weakling an equal chance of survival with the strong; in fact, often a much better chance not only of surviving, but of multiplying, because the strong and virile have to take all the risks, not only in supporting themselves, but also in maintaining the decadent. We have successfully interfered with the selective death-rate which Nature employed in eliminating the unfit; but, on the other hand, we have made no serious attempt to establish a selective birth-rate so as to prevent the race being carried on by the least worthy citizens. The same maudlin sentiment-

ality which often pervades the public not infrequently affects the medical profession. We have often joined forces with self-constituted moralists in denouncing the falling birth-rate, and have called out for quantity regardless of quality. We readily forget that utility, as long ago pointed out by John Stuart Mill, lies at the basis of all morality. We feel compelled by the dictates of conscience to preserve, as far as possible, every human being, no matter how imperfect his intellectual and physical development. Sickness and distress make all flesh akin, but our object should be to prevent such maladies rather than to imagine that they have been sent by Providence.

We have often assumed the position of guides, philosophers, and friends, but in the main we are individuals who deal with the prevention and treatment of disease, and, to some extent, with the maintenance of health. That is what we are doing, and what we shall continue to do for time immemorial if some of our ignorant legislators, who know nothing and care less about physiological laws, have their way. There are a great many people who think that they can have sixpennyworth of health by the purchase of a bottle of physic. Even the British Government health restorer is at a serious discount, as we are led to believe that ninepennyworth of that refreshing fruit can be had for fourpence. Those who put such a low estimate on the position of the medical profession are very apt to grumble when they discover that the health which they have ruthlessly dissipated often cannot be recovered for money. Notwithstanding the gross ignorance which is rampant in our Legislature, and the failure of many to perceive the future from the past, there is yet a growing consciousness among the more intellectual members of the community that the present state of matters must not be allowed to continue. We must raise up a vigorous, intelligent, enterprising, self-reliant, and healthy race.

THE TRUE EUGENICS.

We must not rest content with the mere treatment of disease; we must instil into the public mind intellectual and physical health. We must continue to deal with the prevention and treatment of disease, but we must also ascend to a higher platform and raise the banner of health with the fervour of a new religion.

We must begin with the unborn. The race must be renewed from the mentally and physically fit; the moral and physical degenerates should not be allowed to take any part in adding to the race. Above all, we must breed for intelligence. The laws of heredity should be widely taught, so that those with hereditary blemishes may consider their moral responsibility in bringing children into the world. If everyone would consider his moral responsibility to the race rather than his own selfish gratification, in a very few generations we might produce a pure, moral, highly intellectual and healthy race. Of course we could not make all equal—there is no such thing in Nature, and never can and never will be, and it is not desirable that such should be—but we could raise the average plane and get rid of the present decadence. I know that in the expression of these views I am coming into direct conflict with at least some of the Churches, of which there are almost as many varieties as there are human beings. The majority preach in favour of quantity rather than quality; they advocate a high birth-rate, regard-

(a) Abstract of Presidential Address delivered at the Eightieth Annual Meeting of the British Medical Association, July 23rd, 1912.

less of the consequences, and boldly tell you that it is better to be born an imbecile than not to be born at all. They forget the saying of Jesus of Nazareth that it would have been well for this man if he had never been born. With the man-made morality of the Church I can neither art nor part. There must be a high racial morality based on utility and the greatest happiness not merely of the individual but of the race. Medical men, when they are consulted, as they often are, on questions of matrimony and reproduction, incur a very serious responsibility when they encourage the mating of mental and physical weaklings. It is their duty not to pander to the selfish gratification of the individual, but to point out to every one his positive and negative duties to the race. The time is now ripe for dealing with mental weaklings, and they will be effectually dealt with in all progressive nations. The consciousness of the intellectual in all grades of society is being awakened to the responsibility of individuals to their offsprings, and the advanced thought of the intelligent portion of the community will demand something more than treatment from the medical profession. This will place physiology on a higher plane than pathology, and will require an even more advanced study of the laws of health than of the tendencies to degradation and disease.

LEADERS OF PROGRESS.

The work of Lord Lister, who was a great physiologist, emancipated surgery from the thralldom of tradition, and the great advances which have consequently taken place in that branch of our profession have been the marvel of the age. The progress of medicine during the same period, though noteworthy, has not been so startling. Unfortunately the progress of medicine has been stifled by tradition and by a succession of more or less reputable old gentlemen, who, having attained to place and power by accidental circumstances rather than merit, have not seen the necessity for change. There have been, however, many insurgents who have disregarded the trammels of tradition and led the van of progress. The brilliant advances of surgery were rendered possible by the exclusion of pathogenic organisms, by an improvement in the environment; but such methods are not always possible in internal medicine. We must not only pay attention to the environment, but we must raise the defensive forces of the individual, increase his inherent powers of resistance, and, as far as possible, render him immune to disease. We can point to the remarkable work of Edward Jenner in protecting the individual against smallpox, the work of Pasteur on hydrophobia, of Koch on tuberculosis, and more recently the epoch-making work of a Liverpool man, Sir Almroth Wright, on the prevention and treatment of many infectious diseases. Some of the greatest advances in modern times have been with regard to the prevention and treatment of infectious diseases, and as prevention is generally looked upon as more important than cure, the part played by medical officers of health must become more prominent. The improvements which they have effected in sanitation and in the segregation of disease have been of great advantage to individuals, but it is very doubtful whether their efforts have been equally beneficial to the race. They have largely succeeded in abolishing cholera, typhus, and typhoid fever by getting rid of the sources of infection and thus limiting

the incidence of these diseases, but they have in no way added to the immunity of the race or lessened the susceptibility of the individual. With measles, scarlet fever, and whooping cough and influenza there has been less success, but from the general experience of those diseases by our race it seems that Nature has gradually established a use-acquirement, and consequently the virulence and fatality of these diseases is becoming much less. Notwithstanding all sanitary improvements, the incidence of diphtheria has actually increased, but by antitoxic treatment the fatality has been greatly lessened. If we could only abolish the tubercle bacillus in these islands we could get rid of tuberculous disease, but we should at the same time raise up a race peculiarly susceptible to this infection—a race of hothouse plants which would not flourish in any other environment.

GENIUS AND NERVOUS TROUBLES.

The idea that insanity and genius are closely allied has still so strong a hold on the public mind that many would not interfere with the insane in the hope that some day they may breed a genius. Those who adhere to this ancient and in the main ill-founded belief do not know what constitutes a genius; they ignorantly mistake eccentricity, or uncontrolled and ill-regulated mental activities, for genius. There is not much danger of intellectual visionaries being disturbed in the present day; there are many of them at large, and more knaves than fools among those who batten on an ignorant and trusting public. The higher the intellectual evolution the greater the number of geniuses that are likely to be produced. There must be inherited innate qualities capable of development; a favourable environment will contribute to such development, but it can never create a genius. You cannot gather grapes from thorns nor figs from thistles. The feeble-minded individuals are a growing incubus on the nation, and should be dealt with in the most humane manner by their sterilisation or segregation. It is for the nation to decide which method shall be adopted, but the latter will comport best with the general feeling of the community. There are some who contend that an increase of the celibate population would be a menace to society, but a society which could not cope with such a feeble menace would scarcely be worthy of existence. Moreover, what about the enormous numbers of women, and of men to a less extent, who are forced to live lives of celibacy by the present artificial state of society. Most of the hereditary nervous diseases could be eliminated and the numerous neuroses could be checked by removing many of the causes that favour their development, and by encouraging the reproduction of the race by individuals with stable nervous systems. For the normal activities of the mental attributes you must undoubtedly have a healthy and properly nourished nervous system. It not infrequently happens that men with brilliant intellects may also have inherited or acquired physical defects, and their will power may be able to control and direct the operations of the mind, but it is within the experience of most intelligent individuals that the best mental work is accomplished when in sound health.

THE PATH OF PROGRESS.

We have come from Hippocrates onwards with a long tradition of healing, much of which the public has taken in good faith, and usually in

blessed ignorance, but whither do we go? My friend Professor Benjamin Moore would say the Dawn of the Health Age is upon us, but I trust the dawn and the noonday of the future will be much brighter than any picture which he has portrayed. We do not want a race of gently-reared hot-house plants, which his system would imply. We want a race of men. We want to uphold the saying of Disraeli that "Man is not the creature of circumstances; circumstances are the creatures of man. We are free agents, and man is more powerful than matter." We wish to say with Emerson: "Life must be lived on a higher plane—we must go up to a higher platform, to which we are always invited to ascend; there the whole aspect of things changes."

The profession that has made the greatest strides during the past half-century has been engineering, with its allied sciences of physics and mathematics, yet the medical profession has to deal with a much finer piece of mechanism than anything which has ever been constructed by the hands of man. Moreover, we have got the advantage over the engineer, in that our machine is a very durable, self-regulating, and self-repairing automaton—a machine in the construction of which, fortunately, we have had no say. All we have got to do is to study its mechanism and its functions, to regulate the works, preserve their autonomy, and prevent their destruction. On the other hand, a learned member of our profession has recently extolled our labours, and pointed out our difficulties by showing that the works of the human body are covered up, the hatchways battened down, and yet we are expected to find out and set right any defect in the internal machinery. This form of argument would be apropos if our eyesight was the only sense which we possessed, but the physiology of the body is fairly well understood, and methods of arriving at a correct solution of most problems are at hand; the difficulties are in the application of the knowledge which we possess. We cannot too strongly insist on the higher teaching of physiology, but this necessity is not yet generally recognised even by the General Medical Council.

The path of progress which I have tried to point out will in the future devolve on such great associations as the British Medical—associations which have got no selfish interests to serve, but which have only the honour and dignity of the medical profession and the welfare of the public at heart. We often hear such bold statements as that the general medical practitioner is doomed, his occupation has gone, and his livelihood has vanished. Those who thus talk have their heaven *in statu quo*—they think there is no blessedness beyond the maintenance of their own ignorance. In my opinion the future of medicine will rest with enlightened and highly-educated general practitioners—men who will look after the health of the community, who will see that mechanism of a high order is produced, and who will see that the machinery of the individual is properly lubricated and not subjected to any unnecessary friction or strain. The enlightened public will look to their medical attendants as guides, philosophers, and friends, both in health and disease.

As has been long advocated by the British Medical Association, we must have a properly-regulated State examination, and the vested interests of corporations must not be allowed to prevail against the public weal. Mere examining

corporations, which have done practically nothing for medical education, and are chiefly engaged in extracting fees from students, should be allowed to retire into obscurity. There is here plenty of good work for an able statesman—a man determined to lead and to prevent the present policy of drift. The work of the medical profession should be such as to attract the brightest youths in the country. We must recognise that the outlook of the medical profession, though at present somewhat dismal, is merely a transition stage, which will soon pass away. The sands of time may be running down, but we hope to invert the hour-glass, and trust that there may be a grand to-morrow and a bright hereafter.

"Whatsoever thine hand findeth to do, do it with all thy might; for there is no work, nor device, nor knowledge, nor wisdom, in the grave, whither thou goest."

THE RELATIONS OF THE CIRCULATION. (a)

By G. A. GIBSON, M.D., D.Sc., F.R.C.P.

Physician to the Edinburgh Royal Infirmary.

THE part played by the circulation in the integration of the organism is a natural subject for our thoughts in this city, where the author of the fascinating Silliman Lectures presides over the domain of physiology. The subject must be admitted to be a very large one, as it does not only include the consideration of the connections of the central and the peripheral portions of the cardio-vascular system, but, as already suggested, the relations of the circulation as a whole to the body at large. It comprises the nature of the actions and reactions continually in operation, and the character of the stimuli and responses likewise constantly at work.

The circulation in all the higher animals may be regarded as based upon, or concerned with, four primary groups of principles. It is based upon mechanical arrangements which form the foundation for all its operations. It requires chemical changes, by which it is maintained, and for which it provides possibilities, by transference of matter. It is modified by glandular secretions, which profoundly alter its mechanism and chemical processes. It is affected by nervous agencies which deeply influence the performance of its functions.

Many stages of being in the evolution of the mammal are analogous to phases of life in the development of its individual representatives. The analogies involve structure as well as function. In the newly born there is not merely disproportion in the size of different parts and organs as compared with the adult, but there is also difference as regards function. It would serve no useful purpose on this occasion to dwell particularly on the infantile divergences from the normal of adult life as regards size and weight; but it is of importance to linger over certain deviations in function. The heart of the baby, in relation to the weight of its body, is considerably larger—expressed in percentages of total weight it is almost 0.9, as compared with a little over 0.5 in the adult—almost double; even more striking is the fact that the frequency of the heart beat is much greater, being from 130 to 140 per minute—roughly speaking double that of the adult; the whole circuit of the blood is therefore traversed in a much shorter time—rather more than one-half. It

(a) Abstract of the Address in Medicine delivered at the Eightieth Annual Meeting of the British Medical Association, July, 1912.

therefore follows that the blood is renewed in the tissues of the baby with greater rapidity than in the adult. The total amount of blood, as compared with body weight, is considerably larger in the baby than in the adult; and as the respiratory work, although increasing absolutely with the growth of the body, is nevertheless relatively greater in early life, the absorption of oxygen is much more active than the production of carbonic acid. Metabolism, as the result, is extremely active within a few days of birth.

THE GLANDULAR MECHANISM.

Let me carry you now in thought, before entering upon the glandular mechanism, to some examples of the wonderful nervous influences which preside over the heart and vessels, linking them up with the rest of the body. The whole life of an animal, according to Starling, "may be looked upon as a series of reflex actions." Nowhere is this more obvious than in the relations existing between the nervous and the circulatory apparatus. Of this fact a few simple illustrations may be cited. The idea of profound disorders of circulatory relations through vasomotor disturbances has been gradually growing up since the discovery of the nervous connections controlling the circulation. The observations of Landois on the reflex origin of anginous pain, and of Nothnagel on its connection with vasomotor contraction, as well as the more recent work of Pal on vascular crises, furnish sufficient evidence of this proposition. The receptive field, as Sherrington shows, presents a remarkable contrast between the afferent tracts of the somatic and splanchnic realms; there is a wonderful richness in receptors of the former, or exteroceptive, as compared with the remarkable poverty of the latter, or interoceptive field. Mackenzie and Head have taught us how splanchnic impulses reaching the receptive and perceptive centres are referred by them, as the result of their development, to the somatic area. Nowhere is this truth more clearly manifested than in the various degrees of cardiac pain.

Since the early researches of our countryman, Lower, into the nature and cause of dropsy, the matter has been the preoccupation of many an anxious inquirer. One of the first steps in our modern knowledge of this important subject was the discovery by Ranvier that stasis in a limb is followed much more certainly and much more quickly by œdema if the nervous influence of the part be withdrawn. The close association of œdema and glossiness of the skin with neuritis is now universally known, and is of analogous nature. One of the most important contributions within recent years is that of Ninian Bruce, who has shown that the initial dilatation of the vessels in the early stages of inflammation depends upon the influence of the local nerves, and that it probably is of the nature of an axon reflex.

If we desire an instance in which to find an example of the intimate connection between circulatory and glandular changes, we have not far to seek—it is always to our hand in Graves's disease. Just as in the case of glycosuria, we find hereditary, neurotic, and traumatic factors at work; its invariable association with glandular and circulatory changes, moreover, has long been known. In exophthalmic goitre there are symptoms connected with the digestive system due to catarrhal and hyperæmic conditions; of the glandular system in thyroid enlargement, and less frequent alterations in the thymus, the pituitary, the suprarenal, and the lymphatic glands, as well as the spleen; the blood often reveals the presence of anæmia and, less commonly, of cyanosis, while varying degrees and types of leucocytosis are not infrequently en-

countered; the circulation does not merely reveal the presence of increased frequency of pulse-rate, but of very varying degrees of arterial pressure, while the heart may manifest considerable dilatation, with or without hypertrophy; the renal conditions may be largely modified, not only by the existence of polyuria, but of albuminuria or of glycosuria; the integumentary system may be the seat of the most multiform rashes, and also of atrophic changes particularly affecting the cutaneous appendages; in the nervous system are to be found remarkable divergencies from normal conditions—sensibility diminished, perverted, or increased motility usually affected in the direction of irritable weakness, with exaggeration of the reflexes and responses, diminution of muscular energy, shown by weakness of the movements and tremulousness of the muscles and disturbances of the delicate processes of co-ordination especially as regards the eye, vasomotor and visceral changes, and, above all, profound alterations in the higher cerebral functions—such are the outstanding features of the affection.

THE INTERNAL SECRETIONS AND THE CIRCULATION.

All organs—in fact, all tissues—receive from the blood certain substances, and yield in return others. Every function of the body, even a simple muscular contraction, furnishes material which is restored to the blood; much of this, however, is of the nature of waste. The glands produce special substances, to which alone the name of secretion can be properly applied. All of these glands are now assumed to yield an internal secretion; many, in addition, also furnish an external secretion. The effects of suprarenal and pituitary extracts in the blood vessels have been studied by Argyll Campbell, who found that suprarenal extract causes marked constriction of all the organs, with the exception of those of the heart and lungs. In the heart it produced slight constriction, and this was more evident in the case of the lungs. Pituitary extract contains at least two substances—one causing contraction, and the other relaxation. Each is capable of producing its characteristic effect on all the arteries, except the renal, where contraction is hardly ever obtained, the result being almost always relaxation.

The function of the intermediate part of the pituitary body is to produce a "colloid" material which contains active principles or hormones acting upon the heart, blood vessels, and kidneys. Probably there are several such hormones acting upon blood vessels and kidneys independently, and also acting antagonistically, so that, according to circumstances, either a rise or fall of blood pressure, an increase or diminished secretion of urine, may be produced, and the effects on the kidney may be independent of those on the blood vessels. The hormones which appear to be most active are those which produce contraction of the blood vessels in general, with dilatation of the renal vessels and increased activity of renal cells, but there appear to be others which cause constriction of renal vessels and diminished activity of renal cells: the effects of these latter are generally less lasting. There is also usually an inhibitory effect produced on the heart.

THE ROLE OF THE SYMPATHETIC NERVOUS SYSTEM.

When we consider some of the arrangements by which the sympathetic system is linked up with the cerebro-spinal axis, we can understand how profoundly the central nervous system may be affected by impulses from the periphery, and how reciprocal influences are exerted. Let me mention that the grey rami communicantes appear from experimental work to be composed of fibres which take their

origin in the vertebral ganglia of the sympathetic, and that these rami probably carry vasomotor impulses to the blood vessels of the cord; we can grasp the profound significance of the connection. The fibres of the grey rami seem, indeed, to be relay fibres on the outgoing vasomotor path, recurring backwards and carrying impulses to the vascular supply of the central nervous system. They are, therefore, recurrent, like the fibres described by Magendie as re-curving and re-entering the cord with the anterior roots in order to supply the membranes of the cord with sensibility. Langley and Sherrington consider the fibres of the grey rami entirely post-ganglionic—that is, different from sympathetic ganglia, but intended for distribution to the cord vessels.

A paper of the greatest interest was that recently published by Elliott, who has found that profound nervous influences, such as fright, produce very definite changes in suprarenal secretion. He is led to believe that the suprarenal glands are played upon by the splanchnic nerves in emotional reflexes with delicate adjustment.

Ever since the observations of Oliver and Schäfer upon the suprarenal glands, their substance has been employed by me as the most important remedy in the treatment of Graves's disease. Various mineral and vegetable substances have, in the past, been administered freely in this disease, and in more recent times the blood of dethyroidised goats has been largely used. This latter substance has in my hands, as in those of Murray, proved to be of about the same value as the *pulvis Olympicus* poured upon us by a racing car on a summer day. But in suprarenal extract we have an agent which may be stated fearlessly to have no rival in the management of this affection. Under its employment the rate of the pulse is reduced, the protrusion of the eyeballs disappears, the thyroid gland diminishes, the tremor, along with every other nervous symptom, vanishes, and the patient is restored to health in a way that we never see under any other method of treatment. No one who knows me will accuse me of aught but the most sympathetic attitude towards modern surgery; but this is one of the affections in which it is my duty solemnly to protest against the *furor operativus* which, in this condition, is in the overwhelming proportion of cases absolutely unjustifiable. It is surely far more scientific, as it is certainly much more successful, to trust to the chemical messenger, or hormone, which has the power of regulating the glandular activity responsible for so much of the clinical picture in Graves's disease, than to risk doubtful surgical adventures.

A HOPE FOR THE FUTURE.

We have to put to ourselves the important question, How do these powerful agents produce the changes we have traced? We have seen that they act upon many, perhaps all, tissues. Some probably act on the local processes of renewal and removal, and others by their effects on the muscular wall of the vessels; certain undoubtedly act on the tissues, not directly or even by modifying the vessels, but through the sympathetic system. It seems probable that they invoke nervous influences, consisting in waves of molecular disturbance, which brings about changes by liberation or inhibition. The recent work of Elliott, previously referred to, supports this view.

The results of these interesting advances must enhance our hopes of even more valuable additions to our knowledge, theoretical and practical, at a date not far distant. Their consideration opens a vista of infinite possibilities in the explanation of

normal functions, the comprehension of morbid processes, and the management of diseased conditions. We are still groping after solid facts in the dusky twilight of the dawn, but we doubt not that the brighter radiance of the day will reveal much that is now hidden from our eyes. All that we can now know, all that we can now do, is the result of modern methods of investigation. Led by the whole trend of our education to set a high value on all honest work that explains the scientific problems and assists the practical treatment of disease, the results obtained by devotion to the three sister studies—physiology, pathology, and pharmacology—are to us of paramount importance. It is not given to us all in equal measure to contribute to the advance of knowledge; we, as clinicians, gladly avail ourselves of the labours of those devoted men who illuminate many vexed questions by their experimental researches.

We are like children on a beach of shifting sands: successive tides mould the form of the shore, gradually washing away, but as steadily building up, the coast of the future. So it is with ourselves: with the constant movement of thought, and the alternate advance and retreat of opinion, there are incessant changes. Contemplating these fluctuations, we are sometimes inclined to be impatient, and to wonder whether, after all, there is a real constructive movement.

SOME MEDICAL ASPECTS OF EUGENICS. (a)

By A. F. TREGOLD, L.R.C.P. LOND., M.R.C.S. ENG.

INTRODUCTORY.

GENTLEMEN,—I cannot but be conscious that some explanation, if not apology, is required of me for the choice of my subject this afternoon. For the purpose of this clinic is to afford the opportunity of dealing with matters of importance to us as medical practitioners, and it may well be thought that, although eugenics may be of interest, it can hardly have sufficient practical value to merit inclusion in a post-graduate course.

But I venture to think that such a view is erroneous. Apart from the fact that eugenics has now become a prominent subject of conversation and discussion—and on that ground alone is one which it is eminently desirable for us to have a knowledge of—it is also a science which presents some very important medical problems, problems which are already beginning to engage the attention of the physician and surgeon, and which, in the not distant future, must inevitably come to do so to a still greater extent. We cannot ignore the fact that a great change has taken place in our professional outlook during the past half-century. Whilst by no means neglecting its cure, the trend of medicine is becoming increasingly directed towards the prevention of disease. Eugenics is simply a further extension of this tendency; it is, in fact, preventive medicine carried to its logical conclusion.

This position of eugenics is rapidly receiving recognition. Quite recently a chair in this science has been established in the University of London, and indications are not wanting that other Universities may eventually follow suit. Indeed, I would venture to hazard the opinion that the time will come when eugenics will be a recognised subject of the medical curriculum.

Unfortunately, there is still considerable misunderstanding as to the principles and scope of this science. It therefore seems advisable that I should first of all give some brief account of what eugenics really is and what it proposes to do; we shall then be in a better position to see how intimately it is related to the science of medicine.

VARIATION AND SELECTION.—THE OBJECT OF EUGENICS.

I assume there are two statements with which we shall all agree; *firstly*, that evolution has occurred, and, *secondly*, that further evolution, particularly the racial advance of man, is still possible. I do not think that any well-educated person will nowadays be found to dispute the first statement. With regard to the second, it is, to my mind, inconceivable that all the stupendous progress of the past, resulting, as it has done, in the evolution of man from a single-celled organism of microscopic size and denoting a capacity for development which appears to be almost unlimited, should find its culmination in man as he at present exists, with, as we well know, all his manifold imperfections of body and mind. Indeed, that the limit has not been reached is fully demonstrated by the occurrence from time to time of such persons as Newton, Darwin, Kelvin, Lister, who tower, in their mental development, so conspicuously above the heads of the mass of mankind.

I assume we shall further be agreed that this evolution has resulted from two causes—namely, variation and natural selection. Of the precise details of the process, the *modus operandi*, we may still be imperfectly aware; but that variation and selection are fundamental to all past evolution we cannot doubt, and equally we cannot doubt that they will condition all future advance.

Variation, as I need hardly remind you, is the term used to denote those differences existing between individuals of the same species which are of germinal origin. Many individual differences are not inborn, but are acquired; they result from the action of the environment, in which term I include all the external psychical and physical forces operating upon the organism from the moment of conception; changes of this kind are called modifications. The essential characteristic of germinal variations is their transmissibility to a subsequent generation, on the other hand it seems probable that most modifications are not so transmissible.

It is probable that many of these variations are so slight that their effect upon the condition of the individual is quite insignificant. In other instances, however, they are much more pronounced, and they then result in one of two things. The individual is either placed at a greater advantage in the struggle for existence and is consequently better able to survive, or else he is so seriously handicapped that he is rapidly eliminated by the process of natural selection. The generally accepted view at the present day is that it is in consequence of major "discontinuous" variations of this kind, rather than of minor "continuous" variations, that evolution has taken place in the lower life forms.

The qualities which favour survival in man are different from those operating in the lower animals; but there can be no question that his progress has been similarly due to the survival of the fit and the elimination of the unfit. Much of the selection has been a natural one, but it seems probable that even at an early stage of human development nature was assisted by man himself. Certainly we find that even to-day there are many savage and barbarous races who systematically destroy diseased or deformed offspring. The same practice was enforced by the ancient Greeks and Romans for the good of the community, and Plato, in the Fifth Book of his Republic, advocates it as a necessity for the ideal community.

Since those times, however, a great change has taken place. The growth of humanitarian sentiment has caused the life of the individual to be regarded as far more sacred, and has even made it of more concern than the life of the nation. Not only has judicial infanticide been abolished, but every effort is now made to prolong the life of the diseased and defective. These conditions are, in a large proportion of instances, of germinal origin and transmissible, and consequently the number of these defective persons in the community has increased by leaps and bounds. Natural selection has been interfered with, and no other form of selection has been devised to take its place. The net result is that human evolution has been arrested, the race is at a standstill,

and the history of mankind is simply one long record of the birth, growth, decay, and often extinction of nation after nation.

It is the object of the science of eugenics to remedy this by two methods. *Firstly*, by replacing natural selection by birth selection; in other words, by encouraging the propagation of sound, healthy and "fit" germinal variations, and restricting that of the diseased and "unfit." *Secondly*, by ascertaining the causes of, and adopting measures to prevent, unfit germinal variations in the future.

Now, it is impossible to deny that the science of medicine has played a very prominent part in bringing about the survival of the unfit. The ability of medicine and surgery to save life is now very great, and every day we are engaged in bringing to bear all our knowledge, skill and attention to snatch from the jaws of death lives which we know to be fraught with great expense or even danger to the State, and still greater expense and menace to posterity.

It is true that in the past we have acted in ignorance of these dangers. It is only comparatively recently that we have become aware how the propagation of the unfit, associated as it is with a serious decline in the birth-rate of the fit, is seriously threatening racial progress; but now that our eyes are opened to the fact, it is clearly incumbent upon us to review our position, and the first question I wish to consider is the general attitude of medicine and of the medical practitioner to the survival of the degenerate.

MEDICINE AND THE SURVIVAL OF THE UNFIT.

Regarding this, it seems to me quite clear that the fundamental principle of medicine must be the conservation of life. The value of the life saved, whether much or little, whether a source of good or of evil, is no concern of medicine or of the medical practitioner; these are matters for the community and entirely outside our province. I consider that any relaxation of this cardinal principle would not only be a degradation of our calling and a betrayal of our trust, but that it would also react to the grave detriment of society, and probably be productive of even more evil than that which it proposed to remedy.

It cannot be denied that there are many diseased and degenerate specimens of mankind whose continued existence is a source of grave anxiety and distress to their relatives, of suffering to themselves, and of menace to the well-being of the community. But if the doctrine of euthanasia were once admitted, it would be exceedingly difficult to know where to draw the line; the possibilities of abuse would be enormous, and the arrogation of the right by the individual practitioner, or even by a board of practitioners, to decide whether a patient should or should not be allowed to live could not fail to degrade our profession, to destroy the confidence which is so necessary between the physician and his patient, and to result in the refusal to call in our aid. All this would be to the ultimate disadvantage of society. It is, of course, unfortunate for the racial progress of man that the science of medicine should have contributed so largely to the prolongation of the lives of the admittedly unfit. But this is all the more to the honour of medicine, for it is our fundamental aim to save life. The evil arises not so much from the survival, but from the propagation of the unfit, and this is the concern of the State. It is social science which lags behind and which has failed to keep abreast of the advances of medicine. It is the duty of the State to devise means whereby the injurious effects necessarily attending many phases in civilisation should be remedied. It is not medicine, but those responsible for the management and safety of the nation, who must bear the blame. I cannot but feel that the attitude of eugenics is much misunderstood on this point, and I have therefore thought it advisable to state my firm conviction as a medical man and yet a convinced eugenicist.

Although, therefore, in my opinion, we are not justified in allowing any considerations regarding the good of posterity to interfere with this fundamental duty of the conservation of the lives entrusted to our care, but must leave the general well-being of society and posterity to be looked after by the State.

yet it is evident that we cannot ignore these wider issues. Our profession is rightly regarded as the custodian of the public health; it is concerned with the prevention as well as with the cure of disease, with the future as well as the present, and I cannot but think that it would rightly be held to be guilty of a grave dereliction of duty if, knowing that certain present conditions were seriously threatening the future good of the State, it failed to raise its voice in protest or to indicate the means by which future disaster might be averted.

It is the duty of the science of medicine to draw attention to the evils attaching to the propagation of the hereditarily diseased; it is the duty of the State to take means which will obviate those evils. But I hold that each individual medical man has a similar duty to the patients in his care. No practitioner would neglect to forbid marriage to a patient whom he knew to be suffering from syphilis; I think it is equally his duty to advise against the marriage of a person whom he has good reason for thinking will produce diseased or degenerate offspring.

At the present time it is not always necessary for us to take the initiative in this matter. Many of our educated and more enlightened patients are fully alive to its importance. They are already appealing to us for advice as to their fitness to undertake the responsibilities of parenthood, and it is plainly our duty to be prepared to give them this advice. I regard this as a matter which is peculiarly within the province of the family physician, and one upon which his opinion will be increasingly sought in the future, and this brings me to the next medical aspect of eugenics—namely:—

ADVICE REGARDING MARRIAGE.

The decision as to whether, on eugenic grounds, a person should or should not be advised to marry is always a responsible and often a difficult one to arrive at. A strong attachment may have been formed which is not easily broken. In any case, it is a serious matter to condemn a young man or woman to a condition of lifelong celibacy, and we have to remember that persons who would be willing to abide by an adverse verdict evince thereby a nobility of motive and determination of character which may even to some extent compensate for hereditary taint. Such a decision requires a considerable knowledge of the laws of heredity, and of the facts regarding the transmission of diseases; our knowledge on these points is far from perfect. It necessitates a very careful study of the family history, and such data are often incomplete. It is obvious that the matter is full of difficulties, and the most I can attempt to do in the time at my disposal is to indicate some of the chief considerations upon which such a decision must be based.

On the whole, the available evidence points to the conclusion that the minor modifications which are produced upon the body by the environment are not transmissible; transmission only occurs in the case of germinal changes. Now, diseases are of two kinds; firstly, those which are exogenous, or due to the environment, of which the best examples are the infectious and contagious group; secondly, those which are endogenous, or the result of an innate tendency or diathesis, such, for instance, as hæmophilia and most cases of insanity. Strictly speaking, this distinction is not quite accurate, for reasons into which I need not here enter; it is sufficiently precise for our present purpose. It is obvious that it is only the marriage of those suffering from the latter—the germinal group—which should be prohibited.

It does not follow, however, that every individual who is the victim of some hereditary tendency to disease should on that account be precluded from marriage. Heredity plays a much more important part in the causation of disease, even in those of the exogenous group, than is generally recognised. There are few of us in whom all the organs and tissues are of equal durability; in most the body is liable, as a result of hereditary predisposition, to break down sooner in one system than in another; and if the mere presence of some hereditary tendency

were to be admitted as a ban, I am afraid there would be a very alarming decline in the marriage rate. Take, as an instance, gout; its hereditary nature is well known, but the descendants of even pronounced gouty families are numbered amongst the ablest members of the community, and the actual development of the disease can often be avoided by a healthy mode of life. The descendant of a gouty stock should be advised against marriage with a person similarly tainted, but to bar his marriage absolutely would be absurd, and many other examples of this kind will readily occur to us. It is only when the tendency is of such a nature as to result in serious disablement, to interfere with the discharge of social duties and responsibilities, and to produce civic unfitness that it constitutes a bar to propagation.

I think the best example of innate defect of this latter kind is afforded by the neuropathic or psychopathic diathesis. This arises from the fact that there is probably no other class of disease which has been so clearly proved to be hereditary, and there is certainly no other group which is liable to be attended with such disastrous consequences to the individual sufferer and to the community. This diathesis is probably the manifestation of a devitalisation of the neurone determinant in the germ plasma, and the significance of such a germinal defect is apparent when we remember that the nervous system has come in man to occupy the seat of organic government, that its integrity and vitality are essential for success under modern conditions, and that it is to its further development and evolution that we must in all probability look for any future racial advance. In my opinion, therefore, any individual whose family history reveals the presence of a marked psychopathic diathesis should be precluded from propagation. The manifestations of this diathesis are of many degrees and assume many different forms, which are probably to some extent determined by the nature of the environment; these I cannot here describe, but I may remind you that they include the various forms of insanity, epilepsy, idiocy, imbecility and feeble-mindedness, habitual criminality, often alcoholism, and many other varieties of social incompetence. In the family record of a pronounced neuropathic stock, examples of all these varieties of defect will often be found.

(To be concluded in our next.)

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

CASE OF ACUTE DUODENAL PERFORATION—OPERATION—DEATH.—MR. D'ARCY POWER operated on a working gardener, æt. 40, who had been seized with severe abdominal pain at 1 a.m., 26 hours before operation. The patient appeared to have been a healthy man leading an easy and temperate life. Some years ago, however, he had complained of indigestion, which had never caused any urgent symptoms and he had not called in a medical man. For the last fortnight he had complained of vague pains, which he had thought were due to his heart; they had not been severe enough to stop his work or alter his habits. He was in bed and alone in the house at the time of the attack, but although the pain was sufficiently great to lead him to arouse the neighbourhood, no doctor was summoned till eight o'clock on the following morning. He then looked extremely ill, his pulse was 120, his temperature sub-normal, and he was sweating profusely. Mr. Power first saw him at twelve o'clock, and found the abdomen acutely tender, especially in the right hypochondriac and iliac regions; it was greatly distended, and the patient was so ill that Mr. Power advised immediate operation, having made the diagnosis of perforated duodenal ulcer.

The operation was performed at three o'clock, 26 hours after perforation had occurred. On opening the abdomen, gas and clear serous fluid escaped in considerable quantity. The pyloric end of the stomach and the duodenum were glued to the under surface of

the liver by plastic lymph. Considerable difficulty was experienced in discovering the perforation, which appeared to be situated in the second part of the duodenum and on its posterior aspect. The operation lasted an hour and a half, and was completed by a posterior gastro-enterostomy.

The patient never rallied, and died on the same evening.

Mr. Power said he recently gave a clinical lecture and showed five cases of acute duodenal perforation, in all of which recovery had taken place without any after-trouble. The present case, he pointed out, showed that a condition which is usually easily and successfully treated may present unusual and unexpected difficulties. In his previous cases the operation took less than half an hour, even when gastro-enterostomy was done. In the present instance the mere finding of the perforation took nearly an hour, and yet there was nothing in the previous history to lead the surgeon to suppose that he was dealing with a case of unusual difficulty. The patient, he remarked, as is usual in these cases, was a healthy man in the prime of life, who had had no reason to suppose that he was suffering from so dangerous a condition as duodenal ulceration, and yet the appearances shown at the operation proved that the inflammation must not only have continued for some time, but had certainly extended to the neighbouring structures, which had become extensively adherent. The diagnosis, Mr. Power said, was clear from the beginning since the sudden onset of the pain, the shock and abdominal distension in a seemingly healthy man could have been caused by nothing else but duodenal ulceration.

Mr. Power emphasised the points laid down in his clinical lecture (*Lancet*, July 13th, 1912) with reference to a patient in this category being in the prime of life and believing himself to be perfectly healthy up to the time of disaster, starting out to work without the slightest apprehension. He pointed out that the onset of pain in these cases was sudden and entirely without any exciting cause; as shock passes off the patient may complain of pain in the right iliac fossa, so the case may be diagnosed as one of appendicitis, but the surgeon should remember that in acute duodenal perforation there is always a point of maximum pain in the right hypochondrium. He said that in these cases there was a most misleading point in the manner in which abdominal symptoms subside, which may lead to operation being postponed. The surgeon should decide to operate at once if he thinks he has to deal with a duodenal ulcer.

SPECIAL REPORTS.

THE EIGHTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT LIVERPOOL, 1912.

[FROM OUR SPECIAL REPRESENTATIVE.]

SECOND ARTICLE.

THE business part of the annual meeting closed on Friday last, and, regarded from the scientific standpoint, the work done has been of a very high order indeed. From the medico-political aspect, the general feeling is that the right thing has been done at the representative meeting in calling on "all practitioners to refrain from applying for, or accepting, any post or office in connection with the National Insurance Act, except in regard to sanatorium benefit, provided it is carried on in accordance with the wishes of the Association, until such time as the Government has satisfied the Association that its demands will be met." This resolution was confirmed in the report stage by 117 to 22 votes. As a further safeguard the following rider was also approved: That "before any practitioner undertakes any work in connection with sanatorium benefit under the Act, the conditions and duties of such appointments shall be submitted to the Council for its approval." These resolutions do not, of course, preclude any medical officer of health from

giving advice to public bodies in his official capacity. Practically, the result of the Liverpool meeting is to cause a greater coherence and unanimity amongst the members of the Association, and, indeed, of the whole medical profession with regard to the attitude taken up towards the Government. The final decision has now been given, and the next move now rests with the Government. As might be expected, the discussion of the formation of a public medical service, under professional control, in the section of Medical Sociology attracted a good deal of attention. The weather has been favourable on the whole, and the members and visitors have taken the fullest advantage of the hospitality so lavishly bestowed by the leading citizens of the city.

RELIGIOUS SERVICES.

Speaking at St. Luke's Church on the Wednesday afternoon to a large audience, the Bishop of Liverpool (Dr. Chavasse) said that the wave of materialism that had been felt some years ago by the medical profession had receded, and the dictum of the great surgeon that he had never found a soul in the dissecting-room would no longer be regarded as a scientific pronouncement or as evidence that the soul did not exist. The influence of the mind and spirit over the body was undoubted. Both religion and science to-day were facing the question of faith-healing and the existence of that fantastic and amazing cult which called itself Christian Science, but which was a medley of bad philosophy, confused Christianity, and ecstatic optimism, which cured all evil by denying its existence. There was a great work before medical science in investigating the range of the power possessed by mind and spirit on the body, and the conditions under which it worked. The result of that inquiry would be of peculiar value to suffering humanity. It would remedy superstition, imposture, and grievous abuse. The priest of the body should always work hand in hand with the priest of the soul.

The service for Roman Catholic members was held in the Pro-Cathedral, Copperas Hill, when the celebrant was Archbishop Whiteside. A discourse was delivered by the Rev. H. Lucas, S.J., M.A., who drew a sharp distinction between mere philanthropy (*i.e.*, philanthropy divorced from religion) and Christianity. The former, he said, limited its outlook to the present life, whereas the latter, even while engaged in relieving temporal distress, always looked to man's eternal destiny, and therefore could never regard disease and pain as absolute evils, for they often proved blessings in disguise.

THE PRESIDENT'S ADDRESS.

At 2 p.m. on the Tuesday, July 23rd, the annual general meeting was held in the small Concert Hall, St. George's Hall, when the retiring President, Professor Robert Sandby, M.D., LL.D., introduced his successor in office, Sir James Barr, M.D., LL.D., F.R.S.E., a short biography of whom appeared in our columns last week, and invested him with the presidential badge. A cordial vote of thanks having been voted to the outgoing President, the meeting stood adjourned till 8.30 p.m.

The evening ceremony took place in the Royal Court Theatre, and the scene was one of great brilliance, academic costume being the invariable rule. The foreign guests and delegates were introduced to the President and Lady Barr, and a replica of the presidential badge was presented to Sir James by Mr. Thelwall Thomas, F.R.C.S., the local hon. secretary. At the President's suggestion, the gift was offered to Lady Barr, who accepted the same amid loud applause.

In the course of his Presidential address, a full abstract of which will be found on page 106, Sir James Barr said that the object of the existence of the medical profession, so far as the public were concerned, was hitherto the prevention and cure of disease, the alleviation of human suffering, and the prolongation of life. He lamented the ignorance of some of our legislators, who knew nothing and cared less about physiological laws.

What was all-important for the future of the race was that the medical profession should point out the path along which the moral, intellectual and physical

health of the nation is to be evolved. Above all we must breed for intelligence. Sir James went on to emphasise the work done in preventive medicine by the medical officers of health and by school inspection and school clinics. The future progress of the medical profession lay largely in the hands of enlightened and highly-educated general practitioners, who would see to it that the complex machinery of the individual is properly lubricated and not subjected to any unnecessary friction or strain. The enlightened public would then look to their medical attendants as guides, philosophers and friends, both in health and in disease.

THE ADDRESS IN MEDICINE.

This was delivered in the Arts Theatre of the University, on Wednesday, by Dr. George Alexander Gibson, M.D., D.Sc., LL.D., F.R.C.P., Physician to the Edinburgh Royal Infirmary, upon "The Relations of the Circulation." He pointed out that modern physiology had its birth in the central facts of the circulation which, in the higher animals, was intimately concerned with mechanical arrangements, chemical changes, glandular secretions and nervous influences. Recent researches into the physiology and pharmacology of the internal secretions of the ductless glands had yielded results which had proved most fruitful in the treatment of such diseases as exophthalmic goitre, myxœdema, Addison's disease and even acromegaly. Thanks to the labours of workers in this field, the use of suprarenal extract and the active principles of other glands were often of the greatest service in disease. It was true that pharmacological investigations were often uncertain and even, occasionally, misleading, yet he felt that through these means fresh light would dawn on many a dark place in medicine. (A full abstract of the address will be found on p. 108.)

THE ADDRESS IN SURGERY.

This was delivered on Thursday, also in the Arts Theatre, by Mr. Frank Thomas Paul, F.R.C.S., Ch.M., Consulting Surgeon to the Liverpool Royal Infirmary; a full abstract of which will appear in our columns next week. He dealt mainly with his personal experiences in the surgery of the large bowel, more especially with the various methods of operative procedure for the removal of malignant disease in this region. He felt quite convinced that cancer of the bowel might at times undergo spontaneous cure. It was much easier to make a statement like this than to prove it, and he doubted if he could offer any really convincing proof. The grounds on which he based the assertion were—that for over thirty years he had been removing these growths and submitting them to microscopic investigation; that many cases having the minute structure of cancer had not recurred, though known to have been removed with an insufficient margin of safety; malignant disease of the bowel was very rarely removed during the early stage, yet the percentage of cures was remarkably good, and the duration of life after colotomy for inoperable cancer of the bowel was often prolonged compared with that in inoperable cancer cases, whilst a proportion of the cases passed as malignant cases got well and the tumour disappeared. There was some misconception concerning the relative malignancy of the three varieties of cancer. Usually the big, fungating, encephaloid type of growth was regarded as the most malignant, the colloid as being intermediate, and the scirrhous or ring stricture as the most benign. This arrangement was entirely wrong and out of accord with clinical experience. The colloid was the most malignant type, the ring stricture came next, and the fungating type was the last. It was one of the least malignant kinds of cancer to be met with in the body. The up-growing forms of cancer were essentially less malignant than the down-growing, ulcerating, and shrinking types.

Mr. Paul expressed the view that a well-planned colotomy was not inconsistent with health and reasonable comfort. If the operation were performed earlier, and also done as a preliminary stage of resection greater success would attend these procedures.

THE ANNUAL DINNER.

This was held on Thursday evening, in the Philharmonic Hall, being presided over by Sir James Barr. The interior of this handsome concert hall, the acoustic properties of which are of the finest, presented a most brilliant spectacle, the platform being beautifully decorated with flowers. A large and distinguished company had assembled, including the Earl of Derby (Lord Mayor of Liverpool), the Bishop of Liverpool (Dr. Chavasse), the Mayors of Birkenhead, Wallasey, Bootle and Southport, Sir John Byers, Prof. Armstrong, Sir Ben. Johnson, Prof. Sinclair White, Dr. T. J. Verrall, Dr. Dawson Williams, Dr. E. J. MacLean, Prof. Saundby, Dr. J. A. Macdonald, Sir Chas. Petrie, Mr. Helenus R. Robertson, Mr. F. T. Paul, Mr. John Rankin, Prof. W. Stirling, Prof. Kuliabes, Judge Taylor, Judge Thomas, Prof. Gabbi, Prof. McDill, Prof. Cameron, Prof. Blanchard, Dr. Stewart, Archdeacon Madden, Mr. J. W. Hughes, Mr. Wade Deacon, Mr. Stuart Deacon, Mr. T. E. Sampson, Ald. Roberts, Col. Porter, and many well-known citizens identified with all phases of civic life.

Dr. J. A. Macdonald (chairman of the Council), in proposing the toast of the "City and University of Liverpool," said it was very appropriate that the head of the city of Liverpool, the Lord Mayor, and the Chancellor of the University should be united in one person, and doubly so from the fact that that person was the head of the great family of Stanley—a house that had always been famous in English history.

Lord Derby, in replying, said that Liverpool could justly claim, both in her University and in her Corporation, to merit appreciation at the hands of the medical profession. Liverpool had been the pioneer in establishing a school for tropical medicine at the University, and London had followed. He hoped the time would come when all conditions of men would sink their politics and do in actuality what at the present moment they only did in profession, and that was to do all they possibly could do to secure the health, and by the health the happiness and prosperity of those who lived about them.

The principal toast of the evening, that of "The Association," was entrusted to the Bishop of Liverpool, who claimed the quality of hereditary sympathy with the profession, for during a period of two hundred years his ancestors had been connected with the medical profession. He briefly sketched the connection of the Association with Liverpool, mentioning that this city had a great deal to do with the launching of the Association. He thought he might say that he expressed the feelings of the vast majority of Englishmen outside the medical profession when he said he was sure the public were as anxious that they (the doctors) should receive a living wage as did the colliers, and that the thought of their noble and beneficent profession being on half-pay, starved and straitened, was abhorrent to the minds of every Englishman and every Britisher.

Dr. Ewen J. MacLean (Chairman of the Representative Body), responding, said that the last time they met in Liverpool the membership of the Association was 10,000, and now the membership was 25,000, they having added to the roll during the last year 4,000 members. That was one indication of their strength, and an obvious result of the great crisis with which they were at present faced. Their strength to-day did not consist in the terminology of their resolutions or in what was said from time to time in the various sections of their annual meeting; it did not even consist of the forceful rhetoric of their President for the time being. He feared that our constitution was as much misunderstood by the public as we sometimes misunderstood their constitution. He wished to say once and for all that the dominating body of the British Medical Association was the Representative meeting of the Association. He wished to tell the public that the profession were not losing sight of their interests in this matter. If it could be proved to the profession that their demands and their policy were absolutely unjust and unfair to the interests of the public, there

was not a man amongst them who would not set to work to modify them. That point, however, was far from being proved, and it was well that the public should be assured that in that great crisis and great fight the doctors had their interests near to their hearts. Let the public consider what an enormous effort of accommodation the Insurance Act had called upon the profession to perform. There never was a time in the history of social evolution when at such short notice the whole profession had been called upon to accommodate itself to an entirely new condition of things. Much had been said about the breaking off of negotiations, and much had been said which showed that the position of the profession had not been understood. By the term, "breaking off negotiations," they did not mean that for all time they would boycott the Insurance Act. Their point was that such conditions should be granted to them as would enable them to serve and work the basis of benefit of that great Act, not only in their own interest, but in the interests of the country at large. What, then, did they mean by breaking off the negotiations? They meant that something must be done, and done soon, to dispel that distressing atmosphere of uncertainty. They wanted to know what they were going to be called upon to do. They did not know that yet; there had been no definition of it. It was psychologically impossible that the representative meeting at this time could have said in respect of working the Act either "Yes" or "No"—at that time of uncertainty, with so many factors undetermined, to say either one or the other, would be to gamble with the interests of a great profession. "I say this with a full sense of responsibility," said Dr. MacLean, "that in my view the contents of the letter we received from the Chancellor of the Exchequer, through the Commissioners, was well and sincerely meant, but we decided, rightly or wrongly—I think rightly—that it is calculated to prolong again this period of uncertainty. In regard to the proposal of the Chancellor of the Exchequer, it is to be noted that at all events one division of the Association proposed that in the event of its being assented to, my two good friends, Dr. Macdonald and Mr. Verrall, and myself, should be the three chosen to approach the Chancellor and the Commissioners, subject to ratification by a representative meeting. That matter has been decided. We are not going. So far as myself and my friends are concerned, we are not disposed to be a modern version of Shadrach, Meshech, and Abednego. I say in the present state of this great question, it is time that the Government should at once define the duties we are expected to discharge, both as regards the normal medical benefit, and also on the points that are to be regarded as extras."

The toast of the guests was given by Mr. Robert Jones, President of the Liverpool Medical Institution, and responded to by Mr. H. R. Robertson and Prof. Albert Abrams, of San Francisco, and the health of the President was given by Sir John Byers.

During the evening an excellent musical programme was provided by Mr. W. A. Hollis's orchestra.

VARIOUS MEETINGS.

The Irish Medical Schools' and Graduates' Association held its annual summer meeting and luncheon at the Exchange Station Hotel on the Wednesday, under the presidency of Dr. H. Macnaughton-Jones. An attempt to discuss the policy of the British Medical Association by one of the guests was frustrated by the firm action of the Chairman, who declined to allow any speeches except those relating to the toasts.

The annual luncheon of the Continental Anglo-American Society was held on the Thursday, at the Midland Adelphi Hotel.

THE TEMPERANCE BREAKFAST.

This function, now quite a recognised social feature of the annual meeting, was held in the Walker Art Gallery, under the auspices of the National Temperance League, on the Thursday morning. Mr. Alexander Guthrie presided, being supported by Sir James Barr and Professor Mott, F.R.S., and a large company.

The Chairman said he thought those breakfasts

afforded an opportunity of bringing supremely important subjects before people who more than others had the power of influencing their fellow-men in regard to alcohol and its dangers. Whether they were abstainers or were only amongst the almost persuaded, they must all equally recognise what a factor alcohol was in their national life, and how extremely important it was that right and ripe views should be formed in regard to it.

Sir James Barr remarked there was no doubt in his mind that people took too much alcohol; still the fact remained that people were becoming more temperate now. Even at public dinners there was considerably less drinking now than ten years ago. For his own part, he practically never prescribed alcohol in any case of disease, because people very often prescribed too much for themselves. He knew of no disease from which a patient would get on better with it than without it.

Professor F. W. Mott, M.D., in an instructive address, said he was of opinion that intemperance was largely due to the fact that the casual labourer and the casual workman had to live in many instances under most unsatisfactory hygienic conditions, and the great problem before the nation was to try to improve the housing conditions of the poor. There could be no question that a lot of good material was spoiled by bad environment. He looked upon the chronic inebriate as a great danger to the community, and he thought he should be segregated. Continuing, he said he had come to the conclusion that alcohol might be more or less a weed-killer, inasmuch as it killed off those who were susceptible to its influence, or brought them into asylums, where they were prevented from the propagation of their species. If, however, it was a weed-killer, he would ask whether it was not also a weed-producer. Examinations of the stocks of people addicted to drink often showed that in many cases the habit had been handed down to men, or that their parents were subject either to degeneracy or insanity. It was the duty of the State to prevent disease, and he knew of nothing better able to prevent disease and to cope with intemperance.

THE UNIVERSITY DEGREE CEREMONY.

On the Friday afternoon the University of Liverpool conferred honorary degrees upon five distinguished members of the medical profession, the ceremony taking place in the Philharmonic Hall, where a Convocation was held. Lord Derby, the Chancellor of the University, presided, and the recipients of the honours were Professor George Armstrong (of Montreal), Professor George Alexander Gibson, Sir Wm. McEwen, Emeritus Professor Frank Thomas Paul, and Sir James Barr.

The opportunity was taken at the same time to confer the honorary membership of the British Medical Association upon Lord Derby, the certificate being presented to him by Dr. Ewen J. Maclean, of Cardiff, Chairman of the Representative Body.

THE CENTRAL MIDWIVES BOARD.

The Central Midwives Board met on the 27th inst., Sir Francis Champneys in the chair.

A letter was read from the Clerk of the Council referring to the

SALARY OF THE SECRETARY OF THE BOARD, and suggesting that a limit of age should be fixed for retirement. The recommendation of the committee was adopted—viz. (a) That, in accordance with the communication received from the Clerk of the Council, the salary of the present Secretary be increased, as from April 1st last, by annual increments of £25 to a maximum of £750 per annum. (b) That he retire at the age of 65.

N.B.—The question of the Secretary's salary is understood to be subject to revision on the first vacancy.

A letter was read from a candidate who had failed to pass the Board's examination on two previous occasions, and who for the purpose of obtaining a post falsely stated that she had passed the examina-

tion, asking permission to enter for the next examination. It was agreed that the candidate be informed that her certificates of character are void, and that she cannot be admitted to the examination until the Board is satisfied by special testimony that she is a trustworthy person.

It was decided that the correspondence between the Board and the East Sussex County Council with regard to the failure of Sarah Linton to notify on two occasions when she had advised medical help should be forwarded to the Privy Council.

The application of the Norwich Maternity Charity for renewal of permission to hold written examinations there was granted.

The Standing Committee had had considerable discussion over a letter from the M.O.H. for Manchester suggesting that pupil midwives should be obliged to reside with the midwife by whom they are being trained. Miss Paget strongly opposed the idea, and finally it was agreed to reply that the Board is not prepared to amend the rules at present.

A letter was read from a candidate who successfully passed the last examination complaining of the manner in which she had been treated by one of the examiners. It was agreed that no action be taken in the matter.

The Chairman had been in correspondence with the Newport Health Committee and with Miss Barrett, endeavouring to put an end to the constant friction between those parties; as a result it was hoped that there would be no further obstacle to the friendly co-operation of the Newport Training Home and the Health Committee in future.

A letter was read from the County Medical Officer for Cheshire as to the propriety of advertising by a midwife.

Sir George Fordham moved, Mr. Parker Young seconded, and it was agreed that the reply be that the Board is unable to express an opinion on matters which may come before it in a judicial capacity.

Harriet Hayes, Alice Llewellyn, Matilda Middelton, and Jane Nurcombe were removed from the Roll at their own request.

With a view to establishing larger training schools in the future, instead of a number of smaller ones, the Chairman had made inquiries at some of the leading lying-in hospitals as to whether they would be prepared to accept outside pupils.

The acoustic properties of the new examination hall were discussed. Mr. Parker Young complained very much, and said that the constant reiterated command to "speak louder" was apt to make the candidates nervous. The Chairman thought they had not had enough experience of it yet to make any official complaint. It had been suggested that the Board should bring pressure to bear on local authorities in order to make the compulsory notification of ophthalmia neonatorum universal. The Secretary had made inquiries, and found that out of 75 boroughs only 25 had compulsory notification. It was proposed and agreed that in future when a local supervising authority sends up a charge against a midwife of neglect of the rule with regard to the babies' eyes, the Board should inquire whether notification of ophthalmia were compulsory, suggesting that the only way to avoid the recurrence of such neglect was to make it compulsory.

DWARFS.

DWARFS are men in miniature; their organisation, height excepted, is as perfect as that of any other men. But it would seem that they do not procreate dwarfs as might be supposed; their children reach the height of ordinary individuals.

However, say the *Annales de la Science*, it is worthy

of remark that where there is a dwarf in a family, the child that follows is of ordinary height, but the next one is also a dwarf.

The intelligence of dwarfs is not inferior to that of ordinary persons, as the history of the three following would prove:—

Jeffery Hudson was eight years old when the Duchess of Buckingham presented him in a pie to the Queen of England, Henrietta Maria, wife of Charles I.; a little later, to the great surprise of the spectators, he was seen to issue from the pocket of a servant of the palace of gigantic proportions, who had brought him in in this manner to amuse the Court.

In 1644 Jeffery accompanied Queen Henrietta to France, where a German made some slighting observation about him in his hearing. Jeffery felt very much offended, and provoked his insulter to a duel. The German came on the ground with a syringe! This excited the fury of the dwarf, who forced his adversary to engage in serious combat on horseback and with a pistol. The German was killed.

At 30 years of age Jeffery was only 20 inches high, but he then began to grow, and finally attained the height of nearly four feet. He died in 1682 in the prison of Westminster, where he had been thrown for a political offence.

The second dwarf was called Borwilawski and was a Polish gentleman, celebrated for the variety of his talents. He wrote his own biography, and thus became famous throughout Europe. Like Jeffery, he presented the marvellous phenomenon of growth in old age.

The third and last is Bébé, whose skeleton is preserved in the Natural History Museum; his wax statue is still to be seen in the School of Medicine, dressed in the clothes he used to wear when alive.

He was so small when he was born that he was brought to baptism on a plate wrapped in cotton! His cradle was a padded wooden shoe. At five years old he was already formed like a man of twenty, and weighed 9 lb. 8 oz. He was brought to Poland, to the Court of King Stanislas, to whom he became sincerely attached. The King also had a great affection for him and tried to have him educated, but it was in vain. Bébé never learned anything beyond dancing and beating time; he never could be taught to read.

Up to 16 years old he was of a lively and playful disposition, but from that age he began to lose his cheerfulness and a kind of premature old age overcame him. He died at 22, and was then three feet high. He was married to a female dwarf, whose height was also three feet. She lived to the age of 73, and died in Paris in 1823.

BEER YEAST.

Beer yeast, a living organic ferment, is constituted, says Dr. Aural in the *Journal des Praticiens*, by cells more or less ovoid, which breathe and multiply with amazing rapidity.

From a chemical point of view, beer yeast is an alcoholic ferment; it transforms sugar into alcohol and carbonic acid.

As to its therapeutic action, it is due on the one hand to its special fermentation, and on the other to the presence of a ferment combating morbid germs it meets in the organism. Two forms are used in medicine—the liquid, or fresh, and the dry.

The former is well known—a brownish, creamy liquid with a certain odour of beer. Far from being a fixed product, it is a complex mixture composed of numerous kinds of yeast of inconstant therapeutic action, hence preference should be given to the dry yeast.

Beer yeast has been particularly employed in the treatment of furunculosis, anthrax, acne, and other affections of the skin. It acts on the dyspeptic troubles of the stomach and intestines, frequent causes of those tegumentary maladies.

But it is not only here that yeast possesses a marvellous action; in certain suppurations it is a good therapeutical adjuvant. In the little recurrent abscesses of the eyelids (stye) its employment diminishes rapidly the tumefaction; in conjunctivitis the same results are obtained from local applications. Like may

be said of phlegmonous tonsillitis, the lancinating pains disappear and the patients make a rapid recovery. Eruptive fevers have been more or less influenced by beer yeast, especially small-pox, where under its influence the vesiculae dry rapidly and the general symptoms are very much improved. In the gastro-intestinal complications of typhoid fever beer yeast has been given with profit; the same may be said of cholera nostras.

In pneumonia, broncho-pneumonia and acute bronchitis the yeast produces a decrease of the expectoration and the patient recovers, if the drug is sufficiently prolonged, in a few days.

In diabetes yeast has been given with great advantage, as it acts on the glycosuria of alimentary origin, and thus allows the patients to partake of farinaceous foods and bread.

GERMANY.

Berlin, July 27th, 1912.

At the Orthopädische Gesellschaft, Hr. Hans Virchow gave a description of

THE FOOT OF THE CHINESE LADY.

He had interested himself in the matter, as he had had the opportunity of examining the skeleton of such a foot, and he had also examined Roentgenograms of three others kindly placed at his disposal by Dr. J. Fränkel. The examination was made in the following manner: First a plaster of Paris cast was taken in order that the outward form might be retained; secondly, a Roentgen plate was taken from both radial and lateral sides; the soft parts were most carefully dissected, after maceration each bone was carefully compared with a normal bone; the bony parts were then carefully put together; photographs were taken at every stage of the examination, and these were brought to the full size by enlargement.

The X-ray illustrations did but little to illuminate the condition, and, in fact, were in themselves illustrations of the comparative uselessness of them when there was nothing else to depend on. The only direction in which the plates were of use was in showing the spongy structure of the bones. The results of the examination were roughly the following:—The reduction in size was not an irregular one, one without any plan, but all changes were accurately limited locally, and so sharply characterised that two distinct categories could be determined, resulting in two groups.

Whether the diminution in size was due to arrest of growth or in part to atrophy could not be determined with certainty. Direct atrophy from pressure of the bandages could only be determined at two points—the upper part of the back of the calcaneum and the lateral side of the fifth metatarsal bone. There was hindrance to growth from pressure of the bones on each other. There was also nutritive atrophy, also atrophy from absence of use in the parts.

The malformation was of two kinds—flexions and rotations. The following was observed at the joints:—Extreme gliding of opposed joint surfaces, thinning of the cartilage over the bones, here was a curious knotting or knobbing of the free lying cartilages, limited to the dorsal surfaces of the bones from the second to the fifth. The ligaments were in part displaced and shortened, but otherwise normal.

The muscles were more reduced in volume than would have been expected; they had a very delicate appearance. The substance of the muscles was, however, perfectly sound.

There appeared to be nothing that could be said to be pathological beyond the knotty cartilages of some of the joints. All the rest were, it was true, deviations from the normal, but there was no condition that could have been called morbid. The observations were instructive as regarded other deformities. In the foot of the Chinese lady there was nothing of a pathological nature; all was caused by mechanical means. In the case of other deformities, on the other hand, there was almost always a disease that set up the deformity, and the total end product was too often looked upon as pathological. This was not justifiable.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

RESIGNATION OF PROFESSOR GREENFIELD.—Professor W. S. Greenfield, who has occupied the chair of Pathology since 1881 in the University of Edinburgh, has resigned his position, the resignation to take effect on September 30th. His resignation will probably lead to a complete reorganisation of the Pathological Department in the University. Hitherto the Professor of Pathology has always had charge of wards in the Royal Infirmary, and has been one of the Professors engaged in teaching clinical medicine. In the future other arrangements will have to be made, as, owing to the specialisation of pathology, it is no longer possible to unite the two branches of medicine. It is understood that money, amounting to some £30,000, is now available for the foundation of a chair of Bacteriology, and presumably the Pathological chair will be divided into two—a chair of Pathology proper, and a chair of Bacteriology. It is also obvious that in the interests of pathological teaching in Edinburgh the Professor of Pathology ought to be at the head of the Pathological Department of the Royal Infirmary, instead of, as at present, having no direct connection with it. It is therefore expected that some arrangement involving this will be come to. As the new Professor, whoever he may be, will in all probability not teach clinical medicine, a proposal is being mooted for creating a Professorship of Clinical Medicine. It should be explained that at present there is no chair of Clinical Medicine in the University. The present arrangement is that certain of the Professors hold wards in the Royal Infirmary by use and wont, and at the pleasure of the managers, and that they teach Clinical Medicine. As, owing to the new arrangement, the number of these Professors will be diminished by one, two possible courses are open. The University may either appoint one of the ordinary physicians to the institution to be a University Lecturer on Clinical Medicine, or they may create a chair of the subject. In the former case, of course, the holder of the Lectureship would not enjoy the status of a professor. On the other hand, were a Professorship created the holder of the office would be in the position of having to create an entire department, and this seems, on the whole, to be the best solution that could be arrived at. A suggestion has been made that the holder of the prospective chair (if, indeed, one can speak so definitely on a subject which is entirely in the air) should be required to give his whole time to it and withdraw from practice. Whether it will be possible to get anyone of sufficient standing to undertake the work on these terms seems very doubtful. In any case, the present occasion is one in which the teaching of many of the most important branches of medicine is involved, and it is to be hoped that no vested interests will be allowed to stand in the way of a well-thought-out plan of settlement.

ANNUAL REPORT ON THE HEALTH OF EDINBURGH.—From Dr. Williamson's report for the year 1911 it appears that the death-rate was 14.4 per 1,000—the lowest in the annals of the city. Cancer takes a prominent place in the causes of mortality, the deaths from this disease being actually more than those from phthisis—405 as against 392. The number of notifications of infectious disease, excluding phthisis and cerebro-spinal meningitis, fell considerably short of previous years, reaching only 1,967, or 6.1 per 1,000, as contrasted with 7.1 during the previous year. The largest number of notifications referred to scarlet fever (1,075), while enteric fever accounted for only 31 cases. Edinburgh is rapidly becoming immune from the latter disease. The adoption of the Notification of Births Act and the systematic supervision and visitation which follow it have reduced the infantile mortality to 115 per 1,000. Phthisis notifications are on the increase, probably on account of earlier and more accurate diagnosis. The population of the city, as determined by the census

last year, was 320,318 (143,436 males and 176,882 females). The progress of the population of the city has undoubtedly received a serious check. The 6,819 births registered work out at 21.2 per 1,000—only 691 for every 1,000 expected. A feature which is rather peculiar in the birth statistics for the year is the reversal of the balance of the sexes, the females, contrary to general experience, being in excess of the males as 103.9 to 100. The mortality from infectious disease has not fallen materially. Deaths from tuberculous diseases amount to 182 per 100,000, compared with 256 in Greenock, the highest, and 167 in Paisley, the lowest, in Scotland. In view of the dwindling records of deaths certified as due to alcoholism, a comparison has been made of the mortality resulting in recent years from cirrhosis and other diseases of the liver. Last year there were 28 such deaths, a reduction of nine on the average of the preceding five years.

NATIONAL INSURANCE ACT.—The decision of the British Medical Association to suspend negotiations with the Government is welcomed in Edinburgh. It is felt that it is the only possible course under the circumstances. There is also very general approval of the action taken in reference to sanatorium benefit. From every point of view it would have been disastrous to have boycotted this because it is impossible to work the ordinary medical benefit—such, at least, is the view held here.

DR. G. A. GILSON.—The honour which the University of Liverpool has conferred on Dr. Gilson is universally approved. Dr. Gilson is deservedly popular in both lay and medical circles in Scotland, and all his numerous friends and admirers are delighted that he should have been so sought out for distinction.

BELFAST.

PUBLIC HEALTH.—The death-rate last week in Belfast was 14.5, and except for a few cases of scarlatina and diphtheria the city was free from zymotic affections. No case of typhoid was reported, though if the present close and warm weather continues we can hardly hope to escape it.

THE INSURANCE ACT.—It is satisfactory to be able to state that all the medical practitioners of the city have signed the undertaking drawn up by the Dublin meeting, and no refusals have been met with. Notice is being given to the various societies as to the termination of their agreements with medical men. Rumours of large schemes for sanatoria are current: it is said that the Corporation is going to take over the Abbey Sanatorium from the Board of Guardians and further develop it. The public generally seem hardly to have realised the importance of the movements on foot, but medical men are taking a deep interest in them, and also in the various appointments connected with them. At Londonderry the Mayor presided at a special meeting of the Public Health Committee to consider the sanatorium question, and he begged the members to take plenty of time and do nothing rashly. He said that the present Foyle Hill Hospital cost about £1,500 a year for an average of three or four patients, and he calculated that a sanatorium for at least twelve patients would cost another £2,000 or £2,500 per year. The income under the Act would not nearly meet this. A subsequent speaker ventured to doubt the accuracy of the Mayor's figures, and said that provision could be made on a cheaper scale.

STREET TRAFFIC.—A number of accidents, some of them serious, have lately occurred in connection with motor traffic in our streets, and as a large proportion of medical men now do their work in motors, they naturally take an interest in the traffic question. A London visitor who has been driving through the city with a local medical man says that Belfast is the worst regulated city, as regards traffic, that he has ever been in, and that he would far rather drive his car through the City of London than through the streets of Belfast. The ordinary vanman seldom, if ever, signals to those behind him, and is often seated so far back under the hood of the van that he cannot even see to the sides, much less behind. Police regulation needs improve-

ment and extension, and the time seems to be ripe for some public movement to improve our streets. There is really no excuse for their being bad, for, on the whole, they are wide and well kept, with few awkward corners.

DEATH OF DR. HAMPTON DOUGAN, I.M.S.—Much sympathy is felt with Dr. George Dougan, of Portadown, at the sad death of his eldest son, Dr. Hampton Dougan, a Captain in the Indian Medical Service. He had lately been stationed in Burma, where he contracted blood poisoning and died last week. Captain Dougan was educated in Dublin, and graduated at Trinity College in 1900.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

MR. SEWILL'S EVIDENCE BEFORE THE SELECT COMMITTEE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If you think that a brief statement of the case which I set before the Select Committee on Patent Medicines, to which you so kindly refer in your leader of to-day, is likely to interest your readers, perhaps you will publish this letter. I appeared as a witness on behalf of the British Medical Association. My instructions were to affirm the statement that the traffics under inquiry are almost entirely fraudulent; that they give rise to a vast amount of preventable suffering and misery, and form the direct and indirect causes of a considerable mortality. I was to strive to prove that newspapers which derive great incomes from quack advertisements are either aware of these facts, or display more or less culpable negligence in not taking notice of information on the subject which is constantly thrust before their eyes, even, in some cases, by their own editors and paid contributors.

I began by pointing out that the character of the trade in quack medicines and apparatus had been fully exposed in the civil and criminal courts of every grade during the past fifty years; that it had been constantly dealt with in the *MEDICAL PRESS AND CIRCULAR* and in all medical papers, and particularly in the "Secret Remedy" articles in the *British Medical Journal* and in the "Quarterly" number of that journal. I next showed that many of the leading daily papers had on their staffs medical editors, and that these were allowed from time to time to stultify themselves in articles exposing and denouncing forms of quackery advertised and bebuffed in the same pages; and I handed in to the Committee numerous examples of these articles and of the advertisements and puffs to which I referred. I next showed that the same remarks applied to the leading provincial dailies, and I produced evidence that inferior papers, both in London and the country, justify their conduct in accepting the most fraudulent and vile advertisements by the plea that similar announcements appear in leading journals. I next spoke of the class of anti-scientific papers that devote themselves more or less to disparagement of the medical profession and depreciation of medical science, and showed that the coarsely fraudulent character of the advertisements with which they fill their pages can be demonstrated incontrovertibly by chemistry alone to any intelligent man, although devoid of physiological knowledge. From this I passed on to speak of certain papers that proclaim as their special function the exposure of humbug and fraud. I presented articles from these prints denouncing certain impostures, and handed in fraudulent puffs and advertisements from the same issues. Next I referred to certain papers that exclude quack advertisements, and pointed out that if these papers, some of which certainly have neither medical editors nor contributors, find no difficulty in discriminating there can be no excuse for the conduct of many of their contemporaries. I pointed out that the whole British Press assumes the rôle of censors of morals, guardians of the welfare of the poor, pro-

tectors of the honour of the nation, and showed that the simple and suffering people take the appearance of advertisements in high-class papers as a guarantee of the good faith of the authors.

My evidence did not call forth a single hostile question. It is satisfactory to know that the whole of the testimony is being printed verbatim, and in due course will be published in the form of a Blue Book.

Incidentally the inquiry is disclosing the fact that a vast amount of practice by unqualified quacks is carried on under the cloak of the trade in nostrums and bogus instruments; and altogether a mass of evidence will be gathered which ought at least to compel the attention of the legislature. The Select Committee is instructed to report to the House as to whether they consider legislation is called for. They cannot in my opinion, fail to recognise the need for new laws to deal with the gigantic evils into which now for the first time an authoritative inquiry is being systematically conducted.

I am, Sir, yours truly,
HENRY SEWILL.

The Old Rosery,
Earlswood Common,
July 24th, 1912.

ARTHRITIS DEFORMANS AND A PURIN-FREE DIET.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read Mr. Kellett Smith's article on arthritis, published in THE MEDICAL PRESS AND CIRCULAR, July 17, 1912, with great interest, and congratulate him on his success.

For many years I have held that arthritis deformans is not the hopelessly intractable ailment, or symptoms complex, some would have us believe.

I hold that it is produced by the toxins of micro-organisms and the by-products of imperfect metabolism of foodstuffs, for the most part. Of course, poisons of other kinds may contribute such as nicotine, alcohol, lead, etc.

I find it difficult to believe that purins in their normal condition act as powerful irritants. I do not think they do so unless digestion is impaired and they are changed into poisons either by the vitiated secretions of the digestive organs, the toxins of micro-organisms, or both.

A mucous membrane in a state of catarrh is laden with germs and toxins, it is therefore impaired and not in good condition for performing its natural functions of secretion, absorption and elimination.

Year after year I find authors persistently ignoring lingering infections. If a mucous membrane is catarrhal, it is retaining the germs of some previous infection, such as influenza, or is impaired by the toxins of germs lingering in some other part of the system.

I hold strongly that all infections linger indefinitely and are the basis of all chronic illness. That the typical germs cannot be found always by present-day methods is no proof whatever that they do not exist.

If we can promptly relieve a patient's sufferings by regulating his diet, well and good. We should not stop there, however. We should endeavour to rid his system of offending germs. If we can be certain that some particular germ is chiefly at fault, then a suitable vaccine may be tried. The results of this form of treatment are often very disappointing, however.

Two cases have recently come under my notice which seem to illustrate this.

(1) A lady who had suffered from arthritis for over 20 years was treated for a considerable period with a vaccine prepared from germs found in her tooth sockets. She did not improve. Later on she came to me and I treated her by means of continuous counter-irritation; within a month she said she was in much better general health, and could walk with more ease and power.

(2) A lady who had suffered from asthma for many years, and who had become very thin and weak, was treated for eight months with a vaccine prepared from

a culture of Friedlander's bacillus found in the nose. Expectoration diminished and she felt rather better in herself, but a paroxysm of asthma occurred regularly in the middle of the night and again on waking after a few hours' sleep.

With the consent and approval of her usual medical adviser she came to me eventually.

I also treated her by means of continuous counter-irritation. Within two months the asthma paroxysms ceased and she left for home. This was quite recently. I do not, therefore, know to what extent the benefit will prove lasting, but in a number of other cases of asthma, longer under my observation, the improvement has been maintained indefinitely. My opinion is that we should use our utmost endeavours to restore the digestive functions to such a state of efficiency that they can deal with moderate quantities of any kind of food successfully, rather than permanently to adapt food to the powers of the damaged mechanism. I published an article in THE MEDICAL PRESS AND CIRCULAR, May 8th, 1912, on continuous counter-irritation. I trust this letter is not too long.

I am, Sir, yours truly,
W. J. MIDELTON.

Bournemouth,
July 24th, 1912.

INSURANCE ACT—MEDICAL ASPECT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the inspiring leadership of Sir James Barr, whose outspoken opinion of the Insurance scheme every honest thinking person must heartily endorse, the medical profession has decided, with a unanimity that is striking and significant, to be done for ever with the miserable position assigned to its members under contract practice, and to refuse the dishonourable proposals of Mr. Lloyd George in connection with this Act. Much valuable time has been lost by unsatisfactory and unstatesmanlike manœuvring over the medical difficulty; but now that their decision has been announced, the most strenuous efforts must be made by medical men to organise their forces. The profession has issued its ultimatum, and it is only wasting time, and so preparing for disaster, to prolong negotiations which are clearly meant to create and to keep up disunion in the medical ranks. The Chancellor of the Exchequer, with his handsomely paid assistants and Trades Union and other officials, are pushing on their part of the work with tremendous energy, and that work will assuredly tell when the medical panels are made up unless the members of the profession are organised *at once*. We should be working as strenuously as they are to have our forces thoroughly and completely organised, for according to the thoroughness and perfection of our organisation will be its usefulness and success. The great and important point *now* is to lose no time in completing this organisation, for those medical men who have not yet signed the "pledges" are much more likely to do so now—six months before any action can be taken—than they will be at the end of the year, when it is the end of battle and their forces are disorganised. And it is quite certain that with a perfected organisation, the medical profession will get the fair and reasonable terms asked for long before the end of the year. But an *immediate* perfecting of organisation is absolutely essential, and to obtain this strong measures must, if necessary, be resorted to. For the guidance of those gentlemen in charge of the agitation I would suggest action on the following lines:—

1. Intimate that by a certain date—say, 31st August—all pledges must be sent in to the proper quarter. After that date the names of all members of the profession who have not "pledged" will be published.
2. Members of the profession to pledge themselves not to call in "unpledged" consultants. Consultants to pledge themselves not to meet "unpledged" members of the profession. This is a most important point, and is strongly emphasised by Dr. Russell, of Edinburgh.
3. Members of the profession who have not already done so, to pledge themselves not to go on the medical

panels for insurance work, not to do any Friendly Society work after the termination of existing yearly contracts on December 31st.

4. Get all newly qualified men, those recently qualified, and those to be qualified at the final examinations before December 31st, to pledge themselves as in No. 3.

Members of the profession can easily see that if they loyally, faithfully and unitedly support each other as above, their reasonable demands will very soon be granted, for the Act cannot be worked without them. It has already been shown that there are ample funds to pay much more than an 8s. 6d. capitation fee, but surplus funds have been held up as bribes to insured persons in the form of "additional benefits," therefore the doctors must suffer. The matter lies entirely with the profession, which has only to present a firm and united front in order to succeed. But the party *must* be united—that is absolutely necessary; and that member of the profession is not to be envied who does not, at the critical time, form one of the party. As for the poor insured persons, whose contributions are now being levied under very shadowy and uncertain conditions, they are much to be pitied if the medical difficulty is not soon solved. For if any medical men will be found mean enough to betray their party, they can only be classed as among the "undesirables" of the profession.

I am, Sir, yours truly,
ANGUS MACPHEE, M.D.

Glasgow, July 27th, 1912.

N.B.—There is a guarantee fund to compensate those members of the profession who may suffer loss through their pledges. This fund is already largely supported, and will without doubt be considerably added to if energetic measures are adopted to organise the profession. As stated above, the guarantors will not be called upon to pay if medical men stand by each other shoulder to shoulder.—A.M.

OBITUARY.

MR. E. STANMORE BISHOP, OF MANCHESTER.

We much regret to announce the death of Mr. Edward Stanmore Bishop, which has taken place at Manchester, in his sixty-fifth year. The deceased, who had been F.R.C.S.Eng. since 1884, studied at Manchester and the London Hospital. Mr. Bishop was widely known as an operating surgeon in the North of England, having been attached to the Ancoats Hospital for many years. He was also specially interested in gynaecology, and he was operating surgeon for diseases of women at the Jewish Memorial Hospital, Manchester. He was President of the Manchester Clinical Society and Vice-President of the Manchester Medical Society. He was the author of numerous works on gynaecological and surgical subjects, many of which have had an extensive circulation in America as well as in this country. Mr. Bishop was a member of the Council of the Royal Society of Medicine.

DR. LOUISE APPEL, OF BOMBAY.

The death has taken place at Madanapalla, Madras Presidency, on July 22nd, of Dr. Elizabeth Louise Catherine Appel. The deceased took the B.Sc.Lond. in 1886, becoming M.D., B.S. in 1894-5. She was formerly attached to the staff of the National Anti-Vivisection Hospital, and she had held the posts of medical registrar and assistant anaesthetist at the Royal Free Hospital, house surgeon and lecturer at the Clapham Maternity Hospital, clinical assistant at the New Hospital for Women, lecturer on obstetrics and gynaecology to the Queen Victoria Jubilee Nurses, and demonstrator in anatomy at the London School of Medicine for Women. She was the author of "How to Become a Certified Midwife," "The Bishop of London on Theosophy," a translation of Dr. Kleinschrod's "The Inherent Law of Life," and a paper on "Feeling and Emotion in Eastern and Western Psychology: Their Bearing on Crime and Insanity."

REVIEWS OF BOOKS.

WHITLA'S DICTIONARY OF TREATMENT. (a)

THIS well-known *vade mecum* of medical and surgical practice is now a portly volume containing upwards of 1,200 pages of close print—none too much in view of its very comprehensive scope: ringworm of the beard to railway spine, from comedones to cornu, from occlusion of hymen to folliculitis decalvans, with every intermediate stage. We are tempted to question the utility of burdening the pages with synoptic descriptions of major operations. Even medical missionaries, with whom the work is very popular, probably carry round at least one text-book on operative surgery, and in any case the instructions would hardly suffice to guide a novice.

One of the qualities of a practical work like this one is to tell what to do in emergencies—the morbid condition may or may not admit of curative treatment, but something must be done, certain measures are expected to be applied under particular circumstances, quite irrespective of their therapeutical importance. This is the "small talk" of medical science which keeps conversation going. With it handy for reference one is sure never to be caught napping when confronted with a given set of pathological conditions for the first time. This is both the object of and the justification for such a volume as the present, and, we may add, this object is admirably filled in this, the enlarged and in great measure re-written fifth edition.

EXPERIMENTS ON ANIMALS. (b)

LORD CROMER expresses the opinion that this book will be found useful by a great number of people who are interested in the subject of vivisection but have not time to study the voluminous report of the Royal Commission or the bulky minutes of evidence on which that report is based. The evidence is here re-arranged and grouped under such headings as "Medicine," "Diseases of Animals," "Anæsthetics," etc., but it is given in the words of the witnesses. To the sane and unbiassed mind there is no doubt left of the enormous debt which medical progress owes to animal experiment, and just as little regarding the care and humanity with which the experiments are carried out. The outstanding feature of the evidence is the rather pitiable appearance made by some of the anti-vivisection witnesses, one of whom was told by a Commissioner that he did not seem to have realised his responsibility in appearing at all. Mr. Paget's work has been well done.

SURGICAL CLINICS. (c)

THIS, the first of the series, contains a number of interesting articles on various cases—e.g., carcinoma of the breast, cystadenoma of the breast, pelvic tumour (two cases), nerve anastomosis (two cases), Charcot's disease of the hip-joint, duodenal ulcer, etc. These are all verbatim reports of clinical lectures delivered by Dr. Murphy to the students in the hospital, so, though they may not show great literary merit, they have the great advantage of retaining the lecturer's breezy personality and dogmatic insistence. The result is that the whole volume makes more interesting reading than would a corresponding collection of papers. The illustrations are clear and to the point, and the paper used is good. The work should appeal to a large circle of readers, especially those who are so situated as to be unable to refresh themselves by occasional visits to the clinical hospitals.

(a) "A Dictionary of Treatment." By Sir William Whitla, M.D., Professor of Materia Medica and Therapeutics in Queen's University, Belfast, etc. Fifth Edition. London: Bailliere, Tindall and Cox. 1912. Price 16s. net.

(b) "For and Against Experiments on Animals." By Stephen Paget, F.R.C.S., with an Introduction by the Right Hon. The Earl of Cromer, O.M., G.C.M.G., G.C.B. London: H. K. Lewis, 1912.

(c) "The Surgical Clinics of Dr. John B. Murphy, M.D., at Mercy Hospital, Chicago." Vol. I., part I., Feb., 1912. Price for year of six numbers (one every second month) 35s.; bound in cloth, 50s. Each number about 130 octavo pages. Philadelphia: W. B. Saunders Company.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Paternal Syphilis.—Marshall (*Brit. Jnl. of Children's Diseases*, May, 1912), sets himself to answer the three following questions:—(1) Is it possible for syphilis to be transmitted from the father to the child by spermatic infection of the ovum? (2) Is it possible for a healthy mother to be infected from a fœtus resulting from spermatic infection of the ovum—*i.e.*, by conceptional syphilis (the *Choc-en-retour* of Diday)? (3) Is it possible for a healthy mother to bear a syphilitic child infected by the father without becoming infected herself? For many years the great majority of syphilo- logists were contented to answer these questions in the affirmative; but in the year 1903, Matzenauer attempted to prove that the transmission of the disease always took place from the infected mother. Marshall examines the clinical, microbiological, and serological evidence which our present knowledge can bring to bear on the subject, and comes to the following conclusions:—There is not sufficient evidence to justify the renunciation of the doctrine of the paternal transmission of syphilis. This doctrine is strongly supported by clinical evidence, while theoretical considerations are quite as much in favour of it as against it. As Sir Jonathan Hutchinson remarks: "It is a matter of constant experience that the father of a syphilitic infant is known to have had the disease before marriage, whilst not a symptom has ever been observed in his wife. It is improbable in the highest degree that a large number of married women should acquire syphilis in its primary form, pass through its secondary stages, and yet never know it. Yet this is the supposition we must adopt, not once nor twice, but as an everyday occurrence if we reject the belief that a syphilitic father may beget a syphilitic child quite independently of any previous infection of its mother." K.

Non-Surgical Treatment of Exophthalmic Goitre.—Cohen (*Amer. Journ. Med. Sciences*, July, 1912), examines afresh the vexed question of the surgical treatment of this disease. He comes to the conclusion that the Graves' syndrome is a complex disorder, multiple in its variety and aetiology, and obscure in its pathology. The goitre is an incident rather than an essential in the disease, though its presence usually aggravates the symptoms and often adds new ones. The first element in successful treatment is early diagnosis, and where this is made and followed by skilful hygienic and medicinal management, surgery will only become necessary in about five per cent. of the cases treated. Failure to make such diagnosis results in part from the very name given to the disease, since both the goitre and the exophthalmos are usually late symptoms. The most important element in the medicinal treatment is early and prolonged rest, both mental and physical. Such rest must include the removal of all sources of reflex irritation, including the correction of ocular errors which may be the cause of eye-strain. Fresh air, regulation of the diet and active elimination, with occasional symptomatic medication, must be instituted, and continued for a long period. K.

Treatment of Tetanus.—Parker (*Journ. Amer. Med. Assoc.*, June 8th, 1912), advocates the use of the subcutaneous injection of magnesium sulphate in the treatment of this disease, and records three cases successfully so treated. There have been recorded 24 cases in which magnesium sulphate has been used by subarachnoid injection, and four in which it has been used subcutaneously. Among the former 13 patients recovered and 11 died, and among the latter all recovered. The dosage recommended for intraspinal injection is 1 c.c. of a 25 per cent. solution for every 20 lbs. of body weight. The dose given in

Parker's cases was considerably larger than this, yet no toxic symptoms followed from it. The three cases treated were acute and severe, but not fulminant, and prompt relaxation resulted from the injections. The magnesium sulphate has no specific action, but by quieting the excessive muscular action it permits the patient to obtain more rest and to take food, and thus supports him, while he is manufacturing his own antitoxin. K.

Concussion of the Spine.—Corner (*Med. Chronicle*, June, 1912), reports some cases of concussion of the spine, by which is meant a more or less complete annihilation of the functions of the cord, immediately subsequent to an injury, temporary in character, and unattended by any discoverable lesion. In one case a man was thrown off his horse on his head. He did not lose consciousness, his mind remaining preternaturally clear. He was paralysed in all four limbs, with corresponding anæsthesia. He lay on the ground for about twenty minutes, until somebody came up and gave him some brandy. Shortly afterwards the paralysis and anæsthesia began to pass off. The total duration of these symptoms was about half an hour. He was very ill for some weeks. Six years later a fracture of the axis was discovered by means of X-rays. In another case, an acrobat received an injury to his neck, which was followed immediately by paralysis and anæsthesia of all four limbs and the trunk. The symptoms cleared up in about twenty minutes, the clearance rapidly following the administration of brandy, so that it would appear that the stimulation of the circulation had something to do with the recovery. The man subsequently recovered completely, and a skiagram showed that he had a fracture of the body and pedicles of the fifth cervical vertebra. The two above cases represented a local concussion. By marginal concussion of the spine, the writer means concussion of the segment of the cord at the margin of the injury. This symptom is often masked and rendered permanent by subsequent hæmorrhage. In another case, a man fell from a height, and on admission to hospital, among other signs, anæsthesia extended up to the third dorsal nerve. Next day feeling had returned as far as the umbilicus—*i.e.*, the region supplied by the eighth dorsal nerve. Autopsy showed fracture-dislocation of the seventh dorsal vertebra, with transverse rupture of the cord. In a fourth case there was total anæsthesia to the second dorsal nerve. In 1½ hours the anæsthesia had cleared to the nipple—*i.e.*, the fifth dorsal nerve. *Post-mortem*, the fifth cervical vertebra was found to be dislocated forward on the sixth. The fifth case was similar to the last. In the sixth case, a man of 73 years was kicked between the shoulders by a horse. There was complete anæsthesia and paralysis of the lower limbs and lower trunk. There was no obvious cause of death found at the *post-mortem*. S.

Myositis Traumatica.—Knapp (*Med. Record*, June 15th, 1912), describes a case illustrating his theory and treatment of a class of patient whose condition is frequently diagnosed as muscular rheumatism. The patient complained of pain which was centred in the dorso-lumbar region of the spine. The pain began some two hours after he went to sleep, became of an excruciating character, and of a severity which prompted the patient to call it cramp. He had to get up and sleep in a chair. During the day the pain eased, notwithstanding heavy work. For seven years he had been treated for various conditions as spinal caries, neuralgia, kidney disease, etc. The patient was cured in four days by applying a plaster and making him sleep on a mattress on the floor. The writer considers that the pain indicates passive trau-

matism of the muscle, caused by hyper-extension or prolonged extension of the neck, shoulder, or spinal muscles, as the case may be, following faulty posture in bed, whether due to improperly-arranged pillows or the sagging down of a cheap bed-spring. S.

The Treatment of Acute Puerperal Inversion of the Uterus.—Phillips (*Jnl. Obs. and Gyn. Bt. Emp.*, xxi., 3), has collected 184 cases of this condition, chiefly from the English literature. Of these, 23.4 per cent. died. Of 79 cases in which the uterus was immediately replaced in the presence of marked shock, 30 per cent. died. In 11 cases treated at once, no mention is made of shock and all recovered. In 47 cases in which the uterus was not reduced at once, but the condition became chronic and was treated later, all the cases recovered. In 17 cases death occurred with the uterus unreduced; in many of these death occurred from shock or hæmorrhage before the arrival of the doctor reporting the case. The author, from these statistics and his own experience of three cases, advocates that the shock should be combated first, by saline infusions and injections of pituitary extract and morphia, and then in a few hours, when the patient has rallied, the uterus should be replaced under anæsthesia, at the same time repeating the saline infusion. The delay does not appear to increase the difficulty. In cases where there is no shock, the uterus can be reduced at once. F.

Experimental Poisoning with Chloral Hydrate.—Hopkins (*Amer. Jnl. Obs.*, lxx., 4), from a study of a number of dogs poisoned with chloral hydrate, and examination of the livers and kidneys both of those killed by the poison and those recovered, and also a study of the metabolism as shown by nitrogen excretions both during the action of the drug and afterwards, concludes that chloral hydrate may occasionally produce fatty changes in the liver similar to those produced by small doses of chloroform; that it is impossible to produce necrosis in the liver similar to that found in delayed chloroform poisoning and eclampsia; that chloral produces no histological changes in the kidney, and that it causes an increase in the urinary nitrogen, which may be delayed until after recovery from anæsthesia, and tends to return again to normal. F.

Cornual Pregnancy in the Normal Uterus.—Schumann (*Amer. Jnl. Obs.*, lxx., 4), considers the development and diagnosis of this condition, and reports a case. He says that cornual pregnancy may be spontaneously converted into the usual intra-uterine form, and go normally to term, or the sac may rupture with profuse bleeding from the uterine muscles. The diagnosis is difficult, but can usually be made by repeated pelvic examinations. If it is decided to allow the pregnancy to continue, the patient should be kept under the closest observation in case rupture should occur. If it is decided to terminate the pregnancy, approach should be made by the vaginal route, and the abdomen only opened if it is found impossible to deliver by the vagina. If abdominal section is required, the condition should be treated by conservative methods, so as to retain the parts involved after delivery of the contents. F.

Normal Human Blood Serum.—Welch (*Amer. Jnl. Obs.*, lxx., 4), having considered some of the disadvantages and risks entailed by the use of sera of animals, advocates the use of human serum in the treatment of bleeding conditions, especially in operations upon jaundiced patients, and some septic cases. In the latter it is considered that the serum may supply a necessary element to the patient which will enable the system to overcome the infection by means of its own antibodies. Transfusion is considered of value, but accompanied by risk, and should be reserved for cases of marked depletion from prolonged hæmorrhage. F.

Albumin-Reaction of the Sputum.—For some years past there has been considerable debate as to the value of the albumin-reaction in the sputum as a sign

of pulmonary tuberculosis. Fullarton (*Glasgow Med. Journ.*, July, 1912) reports a study of the sputa in 100 cases. The method he employed was to dilute some 20 or 30 c.c. of sputum with 50 per cent. of water, to add thereto 10 to 15 drops of dilute acetic acid, and to shake the mixture thoroughly. It was then filtered until a clear fluid was obtained. This fluid was tested for albumin by four methods—heat, nitric acid, 5 per cent. solution of ferrocyanide of potash, and saturated solution of picric acid. The tests were employed as in the ordinary examination of urine. In only 8 per cent. of the phthical cases was albumin present or considerable in amount, while in 10 per cent. of the controls this was the case. The controls included heart disease, cancer of the stomach, pernicious anæmia, pneumonia, bronchiectasis, acute and chronic bronchitis. Fullarton concludes, *inter alia*, that (1) in the great majority of cases of pulmonary tuberculosis the sputum contains albumin in considerable amount; (2) in acute bronchitis and pneumonia during the febrile stage, in most cases of pneumonia during the stage of resolution, and in bronchiectasis albumin is present in the sputum in considerable amount; (3) the absence of albumin from the sputum suggests a negative diagnosis as regards tuberculosis. R.

MEDICAL NEWS IN BRIEF

University of Oxford.

THE following candidates have satisfied the examiners for the Diploma in Ophthalmology:—B. G. S. Acharya, J. McC. Browne, A. B. Cluckie, J. N. Daggan, D. V. Giri, W. L. Simpson, and A. E. Verrey.

University of Manchester.

THE following degrees were conferred on July 27th:—

Doctor of Medicine.—F. M. Huxley (awarded gold medal), Catherine Chisholm (thesis commended), H. Coppock (thesis commended), Gertrude Hermine Hickling (thesis commended), W. Wilson (thesis commended), C. Hibbert, F. H. Lacey, A. Spong, and F. G. Wrigley.

Master of Surgery.—E. E. Hughes.

Royal College of Physicians of London.

THE Murchison Memorial Scholarship, founded in 1880 in memory of Dr. Charles Murchison, has been awarded to Dr. William Rees Thomas; and P. Hamill, D.Sc.Lond., and E. G. Schlesinger, M.B.Lond., have received honourable mention.

OFFICERS AND EXAMINERS.—The following Fellows of the College have been elected officers for the ensuing year:—Censors, Seymour J. Sharkey, M.D., S. H. West, M.D., Percy Kidd, M.D., W. Hale White, M.D.; Treasurer, Sir Dyce Duckworth, M.D.; Emeritus Registrar, Edward Liveing; Registrar, J. A. Omerod, M.D.; Harveian Librarian, Norman Moore, M.D.; Library Committee, H. D. Rolleston, L. G. Guthrie, M.D., H. M. Fletcher, M.D., R. H. P. Crawford, M.D.; Curators of the Museum, J. M. Bruce, M.D., S. J. Sharkey, M.D., F. W. Andrewes, M.D., W. Hunter, M.D.

The following were elected examiners in the subjects indicated:—Chemistry, J. M. Thomson, F.R.S., H. C. H. Candy, B.Sc.; Physics, A. H. Fison, D.Sc., H. S. Allen, D.Sc.; Practical Pharmacy, E. I. Spriggs, M.D., W. J. Fenton, M.D., A. E. Russell, M.D., A. R. Cushny, M.D., R. B. Wild, M.D.; Physiology, F. Gooch, D.Sc., F.R.S., J. Mellanby, M.D.; Anatomy, C. Addison, M.P., M.D.; Medicine, W. P. Herringham, M.D., R. G. Hebb, M.D., L. E. Shaw, M.D., J. S. Bury, M.D., H. W. G. Mackenzie, M.D., A. F. Voelcker, M.D., C. Ogle, M.D., R. H. P. Crawford, M.D., W. J. Harris, M.D., H. B. Shaw, M.D.; Midwifery, C. M. Hanfield-Jones, M.D., A. H. N. Lewers, M.D., A. F. Stabb, M.D., G. H. A. C. Berkeley, M.D., J. S. Fairbairn, M.D.; Diploma in Public Health, H. R. Kenwood, M.B., L. C. Parkes, M.D.; Diploma

in Tropical Medicine, F. W. Andrewes, M.D., W. J. R. Simpson, C.M.G., M.D.

NEW MEMBERS.—The following were admitted Members of the College:—E. W. Browne, Captain I.M.S., G. Dansey-Browning, L.R.C.P. and M.R.C.S., Major R.A.M.C., P. Hamill, D.Sc.Lond., L.R.C.P. and M.R.C.S., A. C. Jordan, M.D.Camb., L.R.C.P. and M.R.C.S., J. McPherson, M.B.Glas., Captain I.M.S., B. E. Myers, M.D.Edin., L.R.C.P. and M.R.C.S., H. R. Prentice, L.R.C.P. and M.R.C.S., M. J. Stewart, M.B.Glas., A. W. Stott, L.R.C.P. and M.R.C.S., and W. R. Thomas, M.D.Lond.

Royal College of Surgeons in Ireland.

The following candidates have passed these examinations as undernoted:—

First Dental Examination.—Mr. A. F. Carbery, Mr. G. Dunne, Mr. J. J. Hutton, Mr. J. L. Moulang, and Mr. P. J. Polson.

Final Dental Examination.—Mr. A. J. Bodell, Mr. W. P. Bole, Mr. J. T. Hall, Mr. A. W. Mooney, Mr. J. H. O'Neill, and Mr. S. Robinson.

Primary Fellowship Examination.—Mr. J. Ghosh, Mr. E. N. H. Gray, Mr. F. de C. Keogh, Mr. W. T. McCurry, Mr. D. V. O'Connor, Miss Ma Saw Sa, and Mr. W. R. Watson.

Final Fellowship Examination.—Mr. Richard Charles, Mr. Thomas W. Conway, Mr. Wm. Doolin, Mr. J. J. Hartly, Mr. G. J. W. Tierney, and Mr. Robert White.

Royal Colleges of Physicians and of Surgeons of Edinburgh and Royal Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board, held in Edinburgh, were concluded on the 23rd inst., with the following results:—

First Examination.—The following candidates passed the first examination:—Ethel M. Popplewell, Alexander W. McGregor, John F. Kerr, Frederick J. Jack, Cecil W. Samwell, Santhosham Swaminathan, John A. Tolmie, Nicholas J. Laubscher, James S. Durward, Frank B. Macaskie, Luchhimoni Ghose, Reginald J. T. Malcolm-Gasper, James V. R. Rohan, and Lizzie O'Flynn; and three passed in Physics and three in Chemistry.

Second Examination. The following passed the second examination:—James Bannerman, William J. F. Craig, Douglas C. M. Page, William Walker, James W. Gordon, William D. Bathgate, Alfred Parker, Yeshwant Narayan Kadam, Stewart N. Toulmin, Percy Milnes, and Frederick A. V. Denning; and four passed in Anatomy and ten passed in Physiology.

Third Examination.—The following passed the third examination:—William C. Fraser, Reginald E. Illingworth, Paul L. Manuel, John M. McLachlan, William A. George, Wilhelm S. Rorich, John B. Aickin, Theunis B. Truter, Kenneth Fraser, John Ross, Jan M. Beyers, Ala Ojo Olaribigbe; and five passed in Pathology and three passed in Materia Medica.

Final Examination.—The following candidates having passed the final examination, were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:—Patrick M. Carroll, co. Dublin; Norbert E. Seppelt, South Australia; Cyril M. Willmott, Edinburgh; Thomas R. G. Melrose, Edinburgh; H. W. M. Wallace, Belfast; Devendra Bharadwaja, India; Arthur B. Bull, Cape Colony; Alexander E. Mackenzie, India; Thos. Crawford, Ayrshire; Robert E. Jones, Bangor; James F. Peries, Ceylon; Felix E. Lowe, Jamaica; Gurudas Ram Vohra, Punjab; and two passed in Medicine, five in Surgery, four in Midwifery, and eleven in Medical Jurisprudence.

Royal College of Surgeons of Edinburgh—New Fellows.

At a meeting of the College held July 25th, the following gentlemen, having passed the requisite examinations, on March 20th last, were admitted Fellows:—Bindiganavale Garudachanja Srinivas Acharya, M.B., C.M., Univ. Madras, London, S.E.; Amos W. Bowman, M.B., Ch.B., Univ. Melbourne; Claud J. Brookes, M.B., Ch.B., Univ. St. And.; William F. Buist, M.B., Ch.B., Univ. Edin., L.R.C.S.E. (Triple); Hamilton Drummond, M.B., Ch.B. Univ. Durh.; Gerhard F. Fisser, M.B., Ch.B.,

Univ. Edin.; Hugo Flecker, M.B., C.M., Univ. Sydney, M.R.C.S.Eng., L.R.C.P.Lond.; Davis Heron, M.B., Ch.B., Univ. Edin., Captain I.M.S.; Herbert Hutson, M.B., Ch.B., M.D., Univ. Edin.; John McIntyre, L.R.C.S.E. (Triple Qual.); Satyendra Nath Mukhopadhyay, L.M. and S., Univ. Calcutta, L.R.C.S.E.; James Murphy, L.R.C.S.E. (Triple Qual.); William Roberts, M.B., Univ. Toronto; John C. Robertson, M.B., C.M., M.D., Univ. Glasg.; Archer Ryland, M.R.C.S.Eng., L.R.C.P.Lond.; Neil C. Scott, M.B., Ch.B., Univ. Glasgow; and George H. Sinclair, M.B., Ch.B., Univ. Edin.

Royal Army Medical Corps.

THE War Office last week issued the following list of successful candidates for commissions in the Royal Army Medical Corps at the competition held in London in July, 1912, for which 42 candidates entered:—

R. M. Wright, Bristol Univ., 583; R. B. Price, St. Bart.'s Hosp., 560; J. B. A. Wigmore, Camb. Univ. and St. Thomas's Hosp., 539; *E. C. Lang, Edin. Univ., 530; J. Hare, Durham Univ., 529; E. U. Russell, King's Coll. Hosp., 527; *W. V. Corbett, St. Thomas's Hosp., 523; *R. A. Flood, Dublin Univ., 520; P. M. J. Power, Royal Coll. of Surg., Ireland, 518; *J. L. Huggan, Edin. Univ., 509; *F. C. Cowtan, St. Thomas's Hosp., 505; *C. C. Jones, Birm. Univ., 501; E. V. Whitby, Birm. Univ., 500; G. F. Allison, Queen's Univ., Belfast, and R. E. Porter, London Hosp. (equal), 497; T. H. Balfour, Edin. Univ., 496; *R. B. Phillips, Univ. Coll. Hosp., 496; *R. G. Shaw, Edin. Univ., 494; H. J. S. Shields, Camb. Univ., Middlesex Hosp.; A. L. Urquhart, Edin. Univ., and N. T. Whitehead, St. Thomas's Hosp. (equal), 488; H. F. Panton, Edin. Univ., 486; J. E. Hepper, St. Bart.'s Hosp., A. C. F. Martyn, St. Mary's Hosp., and N. W. Stevens, Edin. Univ. (equal), 485; R. C. Carlyle, Edin. Univ., 471; *L. T. Poole, Edin. Univ., 464; *A. A. M. Davies, Oxford Univ., Westminster Hosp., 463; L. Dunbar, Leeds Univ., 432; *J. C. Sproule, Royal Coll. Surg., Ireland, 429.

*These gentlemen, being in possession of certificates obtained in the Officers Training Corps, were awarded service marks under Paragraph 74 of the Regulations for the Officers Training Corps.

Indian Medical Service.

THE result of the competition for commissions in the Indian Medical Service, which was held last week, is as follows:—

J. D. Wilson, M.A., M.B., Ch.B. Edin., 3,718; L. A. P. Anderson, B.A., B.C., Camb. Univ. and St. George's Hosp., 3,519; W. C. Paton, M.A., M.B., Ch.B. Edin., 3,481; J. B. Hance, B.A., M.B., B.C., M.R.C.S., L.R.C.P., Camb. Univ. and Guy's Hosp., 3,389; S. Gordon, B.A., B.C., M.R.C.S., L.R.C.P., Camb. Univ. and London Hosp., 3,316; G. Y. Thomson, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Guy's Hosp., 3,274; H. K. Rowntree, M.B., B.S. Lond., L.M.S.S.A., Middlesex Hosp., 3,268; B. F. Eminson, M.B., B.S. Lond., Charing Cross Hosp., 3,216; A. Kennedy, B.A., B.C., M.R.C.S., L.R.C.P., Camb. Univ. and Middlesex Hosp., 3,186; J. C. John, B.A., M.B., B.C., M.R.C.S., L.R.C.P., Camb. Univ. and St. Bart.'s Hosp., 3,172; S. D. Ratnagar, B.A., L.M. and S., L.R.C.P. and S. Edin., L.F.P. and S. Glas., London Hosp., 3,157; C. McIver, M.R.C.S., L.R.C.P., Univ. Coll. Hosp., 3,068.

NEW PREPARATIONS.

REGULIN BISCUITS.

WE have called attention on a previous occasion to the value of regulin as a useful vegetable aperient causing a natural and gentle action of the bowels. From the Regulin Syndicate Ltd., 15, Cullum Street, E.C., come some attractive biscuits which contain a larger percentage of regulin than the tablets. They are oval in shape and flavoured with vanilla, and are specially recommended for invalids and young children of weak and delicate constitution. The price of a box of 20 biscuits is 1s. 6d. Children may take a couple or more, and adults four or five, or more, as prescribed.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

THE MEDICAL DIRECTORY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The annual circular for the "Medical Directory" will be posted to the profession on August 1st. We sincerely hope that all practitioners will make their returns to us as quickly as possible, so that the issue for 1913 may be accurate and full of the latest information.

We shall, as usual, publish a few days before Christmas, and we seek the hearty co-operation of the profession in making this effort.—Your obedient servants,

J. and A. CHURCHILL.

7, Great Marlborough Street, London, W.
July 27, 1912.

X. (Hove).—In reply to your enquiry, an aeroplane can mount 4,000 to 5,000 feet, i.e., from three-quarters to one mile. Taking the curve of the earth's surface (which is known), it is easy to calculate the superficies that will be visible. The detection of a fleet 2,500 miles distant from this or any other height would appear to be an impossibility, the statement of Co. Seely notwithstanding.

L. B. L. (Birmingham).—The specific terms of the contract render the reply in the negative unavoidable.

MORE SUO.—We have made inquiries and have ascertained that the book has been out of print for several years.

A. S. S.—Courtesy would demand that a visit should be made, with or without a letter of introduction.

ANOTHER HOME SPA.

The discovery is reported of a medicinal spring at Purton, near Swindon, whose waters are said to possess valuable therapeutic properties. According to an analysis by Dr. Voelcker the Purton water contains iodide of sodium, bromide of magnesium, sulphate of soda, sulphate of magnesia, sulphate of lime, sulphate of potash, carbonate of potash, chloride of sodium, oxide of iron and alumina, with traces of phosphoric acid, soluble silica, making a total solid residue of 348.725 grains to the Imperial gallon, together with 50.4 of free carbonic acid and a trace of sulphuretted hydrogen.

M.B.M.A.—The Royal Society of Medicine is now an assured success. To relieve any doubt upon that point, our correspondent would do well to pay a visit of inspection to the Society's new home, Wimpole Street, W. He will be courteously received, and will, we doubt not, be impressed by what is shown him.

Dr. R. R. R. (Liverpool).—The report on Tuberculosis referred to in our issue of the 24th inst., is published as a Parliamentary Paper and may be obtained through any official stationer or bookseller.

Appointments.

BARKER, L. E. H. R., M.B., B.S. Cantab., School Medical Inspector under the Lancashire County Council.

BOYD, SIDNEY ARTHUR, M.S. Lond., F.R.C.S. Eng., Surgeon to Out-patients at the Hampstead General and North-West London Hospital.

BROOK, ELIZABETH H., M.B., B.S. Edin., School Medical Inspector under the Lancashire County Council.

DRYSDALE, J. H., M.B., B.C. Cantab., Non-obstetric Physician to Queen Charlotte's Lying-in Hospital.

EDMOND, W. S., F.R.C.S. Eng., Surgeon to X-Ray Department of the Salop Infirmary.

GASH, T., M.B., B.S. R.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Snodland District of the county of Kent.

MACGREGOR, D., M.D. Edin., Certifying Surgeon under the Factory and Workshop Acts for the Jedburgh District of the county of Roxburgh.

MAXWELL, R. D., M.D. Lond., Physician to In-patients at Queen Charlotte's Lying-in Hospital.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Garforth (Yorks), Sheerness (Kent).

Royal Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £100 a year. Applications to the Secretary, Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 a year, with board and lodging. Applications to Wm. H. Sands, Secretary.

Staffordshire County Asylum, Stafford.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board and washing. Applications to the Medical Superintendent.

Brixton Dispensary, Water Lane, S.W.—Resident Medical Officer. Salary £175 per annum, with furnished apartments, attendance, coal and gas. Applications to W. Halliday, Secretary.

Macclesfield General Infirmary.—Senior House Surgeon. Salary £100 per annum, with board and residence. Applications to the Chairman of the House Committee.

York County Hospital.—House Surgeon. Salary £100 per annum, with board, residence, etc. Applications to Fredk. Neden, Secretary and Manager.

Births.

GUNN.—On July 26th, at Calf Hall, Consett, the wife of George Gunn, M.D., Neston, Cheshire, of a son.

MASON.—On July 25th, at 49, George Street, Portman Square, the wife of George A. Mason, M.A., M.B., B.C. Cantab., of a daughter.

MOON.—On June 27th, at West Orange, N.J., U.S., the wife of Dr. James F. Moon, of a son.

PRINGLE.—On July 22nd, at 153, Withington-road, Manchester, the wife of Dr. John Pringle, of a son.

RIDOUT.—On July 27th, at Southsea, Hants, to the wife of C. A. Scott Ridout, M.S., M.B. Lond., F.R.C. Eng.—a son.

SCOTT.—On July 26th, at 130, Harley Street, the wife of Mr. Sydney Scott, of a daughter.

STOTT.—On July 28th, at 24, Addison Road North, W., the wife of Arnold W. Stott, M.A., L.R.C.P., of a daughter.

WHEELER.—On July 24th, at 32, Monkstown Road, Co. Dublin, the wife of Dr. Robert De Courcy Wheeler, of a daughter.

WILD.—On July 26th, at Aspinall House, Prescott, the wife of Charles H. Wild, M.R.C.S., L.R.C.P., of a daughter.

WILKINSON.—On July 19th, at Mansfield Lodge, Simla, the wife of Lt.-Colonel E. Wilkinson, I.M.S., of a daughter.

Marriages.

ATHERTON—STOPFORD-TAYLOR.—On July 24th, at St. Hildeburgh's, Hoyalake, Alfred Edward, second son of George Atherton, Esq., Rose Hill, Aughton, and The Firs, Windermere, to Victoria Elsie, only daughter of Dr. Stopford-Taylor, Rodney Street, Liverpool, and Standishgate, Hoyalake.

MAYER—DOUGLAS.—On July 27, at Christ Church, Hornsey, by the Rev. C. J. Sharp, M.A., Wm. Lewin Mayer, L.R.C.P., M.R.C.S., L.M., to Bessie Douglas, only daughter of George Banks, J.P., of Broughton, Hants.

VERCOE—SKINNER.—On July 25th, at the Parish Church, Wimbledon, Richard Herbert, M.R.C.S., son of the late Richard Vercoe, of Bodmin, to Elizabeth (Celic) second daughter of the late Charles Pickard Skinner, Staff Paymaster, Royal Navy, and of Mrs. Skinner, of Queen Alexandra Court, Wimbledon.

WENHAM—ANGUS.—On July 25th, at Heath Street Chapel, Hampstead, Herbert Victor Wenham, M.B., F.R.C.S., of the Union Medical College, Peking, second son of Arthur Wenham, of 11, Beauchamp Avenue, Leamington, to Margaret Elizabeth Angus, only daughter of Charles J. Angus, of 22, Church Row, Hampstead.

WIGRAM—EDWARDS.—On July 23rd, at St. Peter's, Great Haseley, Loftus Edward Wigram, M.B., youngest son of the late Prebendary F. E. Wigram, to Constance Emma Letitia Edwards, youngest daughter of the Rev. W. Gilbert Edwards, Rector of the Parish.

Deaths.

ADAMSON.—On July 23rd, at Labuan, Straits Settlements, Robert Edward Adamson, M.D., son of the late Alexander Rattray Adamson, M.D., of Cirencester, aged 44.

APPEL.—On July 22nd, at Madanapalla, Madras Presidency, Dr. Elizabeth Louise Catharine Appel (Dr. Louise), B.Sc., B.M., B.S. Lond., on the anniversary of the death of her brother, Chas. Willm. Ernest, of the Livingstone-Congo Inland Mission.

CARRUTHERS.—On July 22nd, at Hulton House, Runcorn, very suddenly, William Hodgson Carruthers, M.D., F.R.M.S.

CROCKER.—On July 30th, at The Mount, Wellington, Somerset, after a short illness, Jonathan Crocker, M.R.C.S., late of Stogumber, aged 87.

DAY.—On July 22nd, at Westcroft Square, Hammersmith, Albert Bryan Day, M.R.C.S., L.S.A., late of Isleworth, Middlesex, aged 80.

GRABHAM.—On July 23rd, at Martyns, Witham, Essex, George Wallington Grabham, M.D. Lond., aged 75.

GREAVES.—On July 7th, at Barbados, West Indies, Herbert Stanley Greaves, B.A., M.R.C.S. Eng., L.R.C.P. Lond., only surviving son of the Rev. Canon and Mrs. Greaves, aged 38.

WALSH.—July 20th, 1912, at Clogheen, Margaret Legros Walsh, beloved wife of Dr. W. P. Walsh, as the result of an accident.

NOTES AND COMMENTS.

The Tale of the Tub.

JUDGING from the result of Dr. R. H. Quine's inquiry into the use of the bath by hotel and lodging-house visitors, it would seem almost as though the famous dictum once expressed by an eminent member of the medical profession regarding the use of soap were being seriously taken to heart by the public. There is no doubt that the daily bath habit is, for the great majority of individuals, simply a counsel of perfection, unless it has been formed in early childhood and has become a second nature. Climatic considerations, lack of time and opportunity, all more or less legitimate excuses, are among the chief causes of the failure to practise total daily ablution. Moreover, the accommodation provided in the average house is not sufficiently tempting or commodious to induce a semi-reluctant or half-awakened person to take a plunge into cold water, which, if regularly indulged in, would act as an excellent tonic, and also as a good prophylactic against cold-catching. The more limited sphere of the wash-hand basin is, consequently, preferred by approximately forty millions of our fellow creatures in the British Isles. It is assumed too often that habits of personal uncleanliness are confined to the poorer classes, but an investigation of this character serves to show that a greater reform is needed in the direction of providing increased bathing and washing facilities for domestic use for all sections of the community.

The Home Cultivation of Drugs.

THE President of the British Pharmaceutical Conference, Sir Edward Evans, in the course of his address delivered at the Edinburgh meeting last week, alluded to the fact that the Government of the United States have a bureau of plant industry connected with the Department of Agriculture. He threw out the suggestion that certain plants and herbs used in medicine might be cultivated on the large scale in our own country under the auspices of the Board of Agriculture, and he pointed out that British soil seemed specially adapted for this purpose. It is well known that home-grown digitalis, henbane, colchicum and valerian, among other common medicinal plants, are equal, if not superior, to any produced elsewhere. In a paper read before the conference by Mr. J. H. E. Evans, nephew of the President, the fact is stated that there is as great a demand as ever for the old domestic remedies, such as cascara, podophyllin, etc., so that there would appear to be sufficient selection of material for the cultivator. Private enterprise has done a good deal in this direction,

but there would seem to be a distinct opening for the cultivation of another home industry, which the Government might be well advised to supervise and control. Meanwhile small holders must be content to grow aconite and belladonna under the shade of their own fig tree.

The Income of the "B.M.J."

THE issue of an appeal to the public for support by the British Medical Association does not at first sight strike one as a dignified proceeding, although there may, of course, be much more justification for such a course than that which appears on the surface. It is not altogether clear why the Association should be in want of money, since it enjoys a princely income from a journal having an unrivalled circulation amongst medical men. Were the journal in private hands it would undoubtedly be made to yield a handsome fortune to its proprietors within a few years. There is no apparent reason why it should not yield a similar harvest to its present owners. In saying this we have not the least wish to criticise the editorial management, which is clearly not responsible for extravagance or otherwise in purely business management. Our argument is simply that under private management a similar enterprise would yield a large available yearly profit. Were the right of annual general meeting restored to members there would be a better opportunity of drawing attention effectually to this and other important matters of administration.

A Strikers' Fund.

ONE of the curious phases of latter-day humanity is the attitude of society towards the labour strikers in London. As the result of the collective action taken by the dock labourers and allied industries many thousands of men have been out of work for several months. The society funds available for their relief have been long since exhausted and a vast amount of suffering has been inflicted upon the strikers and their families. Hitherto an organised common action of this kind has been undertaken by the labourers concerned, who have had to bear upon their own shoulders any resulting inconvenience or disaster. In the present conflict between capital and labour the position has been reversed, for society has come to the rescue with overflowing subscription lists in favour of the starving families of the strikers. That is to say—reducing the matter to the terms of simple statement—that the strike is being maintained by the subscriptions of philanthropists and no longer by the personal sacrifice of workers anxious to improve their financial position at all costs!

The Noble Sport of Otter Hunting. It were well for the fervid cult of anti-vivisectionists—as we have often pointed out in these columns—were they to turn their attention to the degrading and revolting cruelty involved in many kinds of so-called “sport.” For the mere purpose of relieving the tedium of a life that is not overburdened with intellectual interests, the country gentleman, aided by his town cousins who can afford a sufficiency of time and money, amuses himself from time to time with highly organised and costly expeditions with the object of killing hares, foxes, otters, deer, pigeons and other creatures. Of all these countryside barbarities it is difficult to conceive any more barbarous than that devoted to the chase of the otter. The strength, fierceness and tenacity of life possessed by that animal enables it to fight for life often for many hours at a stretch, and its fighting prowess is shown by the mutilation or death of various dogs of the pack. From the point of view of dying “game”—that is to say, of putting up a stubborn and resourceful fight—the otter is a godsend to the country sportsman, but it is bound to die in the long run when beset with overwhelming odds by hounds and hunters.

Why not Regulate Sport?

A RECENT account of such a hunt relates how at one point the otter was being killed by the hounds, when two of the huntsmen rushed into the water and literally dragged their quarry from the jaws of the pack. In the struggle the poor animal's back was broken. The witness of the incident thought, naturally enough, that the huntsmen were going to put an end to the otter's sufferings, but their intervention was merely with a view to prolong the amusement. The otter, in spite of its paralysed hind quarters, fought some while longer with the fore part of its body, much to the delight, doubtless, of the men and women who had gone to so much trouble and expense in order to end his existence. We wonder if any antivivisectionists were amongst them, and, if so, whether it occurred to them to apply the test of motive to the common object of their gathering. In any case, it seems not a little inconsistent that the community which legislates for the protection of the lower animals against experiment, conducted with the view of alleviating the maladies of man, should tolerate all kinds of atrocity inflicted in the name of sport.

LEADING ARTICLES.

CELLULOID DANGERS AND THE HOME OFFICE.

LAST week witnessed an important inquest in the City of London upon the bodies of eight girls who died as the result of a fire upon the top floor of a building in the heart of the City. The place was used as a factory, and the business carried on there consisted chiefly of the manufacture of celluloid Christmas cards. There were two rooms, and all the workpeople in the front room escaped by the main staircase and were joined by two of the girls in the back room, but the rest in that part of the premises were cut off by the flames, which spread with extraordinary rapidity. The unfortunate young women rushed up a special staircase exit to the roof, but the flames had already burst through the skylights, and the only way open was to the

back of the building, a projecting block with a sheer drop of fifty or sixty feet on all sides. One or two of the girls were able to escape by means of a plank; some jumped or fell down to the glass office roof below, and of these one escaped with little injury, and one is still alive. The rest were burnt on the roof. The occurrence has been fully investigated by the Coroner, Dr. F. J. Waldo, not only as regards the deaths, but also as to the cause of the fire and the prevention of similar occurrences in the future. During ten years of office the Coroner has investigated about a score of deaths from celluloid fires, so that it is time something were done. The circumstances of the present fire reveal gross and culpable negligence. The fire was caused by a boy sealing a packet of celluloid sheets by sealing-wax lighted at a gas-ring jet. This proceeding would be little more dangerous if it were carried out in a firework factory. There were about 1,000 lbs. of celluloid stores on the premises, and a few minutes sufficed to gut the place and destroy the eight girls. There were no regulations whatever as regards precaution in handling the celluloid. There were no fire drills, the employees had no special warning, there was no fireproof storage, no appliances for extinguishing fire. On the other hand, there were a number of naked lights, live gas stoves used for cooking purposes, and a sealing-wax jet. As regards fire exits, the London County Council did their duty, and after some litigation compelled the owners to furnish adequate exits. There the matter ended, for it seems to have been the duty of no one to see that the fire exits were maintained in proper order. The Home Office, in a letter to the London County Council, signed by a Secretary of State, accepted full responsibility for the safety of the workpeople in this particular factory. The way in which that control has been administered is a revelation as to the slothfulness and absolute inefficiency of Home Office methods. It was admitted in evidence that no register of celluloid factories was in existence, and that the one where the fire occurred, one of the largest in London, was simply described as a Christmas-card manufactory. The Home Office has published an excellent set of draft regulations by the chief inspector, Dr. Whitelegge, for distribution amongst celluloid factories, but no copy of this appears to have reached either the head of the firm or his manager, nor was it ever brought to their notice by any of the factory inspectors on the occasion of their exceedingly rare visits to the premises, in spite of the fact that reckless laxity must have been apparent to a mere tyro in such matters. Needless to say, Dr. Whitelegge's memorandum would carry nothing but a moral advisory weight, but in the present instance the firm was willing and anxious to carry out everything desirable for the safety of their employees. The gross and inept failure of the Home Office to discharge its elementary functions under the Factory Act has been demonstrated by the recent tragedy in the City, and it is to be hoped that the Home Office will agitate

for statutory powers instead of their present useless permissive functions. The jury urged the desirability of a Royal Commission of Enquiry into the whole subject of fatal fires, and the relation of the various authorities to the prevention of fires—a step that, if adopted, would open the eyes of the public as to the need of businesslike methods in some at least of our Governmental departments.

THE SURGERY OF MALIGNANT DISEASE OF THE LARGE INTESTINE.

THE value of a well-timed operation for the relief of cancer of the lower portion of the intestinal tract and the pain and suffering due to cancer is especially evident when that disease attacks the large intestine. Many years of useful life may be granted by a judicious colotomy, for instance, and the patient may even be enabled to take part in public and social life with a very fair degree of comfort and satisfaction. The personal experiences of one who has devoted much attention to this special branch of operative surgery must be regarded as of more value than many text-books, and therefore the remarks made by Mr. T. F. Paul, in his address in surgery, delivered before the British Medical Association at the Liverpool meeting, a full abstract of which we publish this week in our columns, are worthy of the most earnest attention. An address of this kind, embodying the results of a long practical experience, and coming from one who, by virtue of his position, is pre-eminently qualified to judge of the merits and drawbacks of the various operative procedures, cannot fail to be of the greatest service to those whose opportunities are, necessarily, more limited. It will, doubtless, come as a surprise to many to learn that Mr. Paul is firmly convinced that the spontaneous cure of cancer of the colon does actually occur, especially after a colotomy has been performed, and, further, that occasionally no recurrence has taken place when a malignant growth in this situation has been incompletely removed. The varying degrees of malignancy, it was pointed out, have an important practical bearing upon the question of prognosis. Thus, the colloid type of cancer is the most malignant, the hard, schirrous form moderately so, while the soft, fungating variety is the least. Happily, the last-named is the kind most frequently seen, especially in the cæcum and rectum. The operation of colotomy itself is practically free from danger, except in the old and feeble, and when a satisfactory surgical result has been obtained "it only needs a little pluck and a desire to make the best of a disadvantage for any ordinary patient to continue to lead a useful life." Short-circuiting is less objectionable to the patient than colotomy, and whenever possible this is the operation of choice, but the fact remains that a colotomy is almost always necessary for inoperable rectal cancer, for grave obstruction, and for certain forms of colonic ulceration. Excision of the growth itself is to be desired when circumstances permit, and it is in-

teresting to note that the advantages of the glass tube method, described by Mr. Paul in 1892, still appeal to him and to many other operators. As carried out by the originator, the operation takes quite two months to complete, and it is about three months before patients are able to resume their work. With regard to excision of the rectum for malignant disease, a preliminary colotomy is advised in all the more serious cases, for it greatly lessens the risks of total resection. The retention of a portion of healthy bowel in the old situation is considered injudicious, as better results are generally obtained by making a new exit beside the sacrum. Much profit will be gathered from a careful perusal of this address, which reflects in every paragraph the learning and experience of its distinguished author.

CURRENT TOPICS.

The Admission of Laymen to Medical Debates.

IN the report of the scientific work of the annual meeting of the British Medical Association at Liverpool, to be found elsewhere in our columns, it will be observed that one of the sections, that of Tropical Medicine, invited the attendance of representatives of large business firms having offices in the City to be present at one of the debates. The subject down for discussion was that of the sanitation of agricultural estates in the Tropics. The plan of admitting prominent laymen to medical meetings of this kind has been tried on previous occasions when matters of industrial importance have been discussed. There can be no objection whatever to the presence of the heads of large firms and manufacturing concerns at medical discussions when topics closely affecting the health of their employees and the general hygienic aspect of the work done are under consideration. Such individuals would not only derive benefit from hearing the discussion on the scientific side of their particular trade or industry, but their co-operation in health matters would be the more readily enlisted as the result of a combined conference of this sort. It has become quite common to invite some distinguished layman to deliver the opening address at a public health congress, for instance, and, indeed, a great conference on hygiene would be considered incomplete without the presence of some lay official. The Section of Tropical Medicine may therefore be congratulated upon the wisdom of its policy in this direction.

The Expansion of the Royal Society of Medicine.

IT is understood that the Council of the Royal Society of Medicine has decided to form additional Sections of Ophthalmology and Tropical Medicine, and it is anticipated that both of these new extensions will be ready for work by the beginning of the winter session. There is no reason why every single branch of medical science should not be represented at No. 1 Wimpole Street as a component part of the now greatest Society for the advancement of medical learning existing in the metropolis. Many reasons have been given in the past why certain societies have preferred to hold aloof, perhaps the favourite one being a fear lest

the individuality pertaining to the old society should be lost by becoming merged in the larger body. This, however, is a purely specious argument, for a certain amount of freedom, nay, even laxity, is allowed to the various sections, whereby each is at liberty, to some extent, to frame its own by-laws and to impose restrictions as to membership. It is only right that the sectional councils should have a free hand in matters of self-government, but, at the same time, it is the Council of the whole Society which is responsible for the harmonious working of all its constituent parts. Too much liberty in this direction is to be deprecated, for it may easily be taken advantage of by exclusivists and corner-promoters. The more catholic and liberal-minded the regulations for the control of each section the better for the cause of general medical science. Actuated by these principles, we look forward to the time when there will be no need for any other medical societies, special or general—save the purely local ones—for all interests will then be embraced and absorbed by the Royal Society of Medicine.

Dr. G. E. Morrison's Chinese Appointment.

MOST serious students of Chinese contemporary history have known that for many years the *Times* has been represented in Peking by a correspondent whose knowledge and ability have made him the leading authority on his subject throughout the world. Few medical men have, however, been aware that the gentleman in question, Dr. G. E. Morrison, is a member of the profession. He is an Australian by birth, and a graduate—M.B., C.M., 1887—of Edinburgh University. Within the last few days it has been announced that Dr. Morrison has been appointed political adviser to the Chinese Government. This appointment is a new creation. It will put Dr. Morrison in a position of great authority, and if, as seems likely, he will be provided with a staff of highly-qualified foreigners, he may be able to influence greatly, or even to direct the home and external policy of the empire to a happy issue at a time when it so sorely needs steady and enlightened guidance. The *Times* gives a sketch of Dr. Morrison's career. At the age of twenty he undertook a pioneer expedition to New Guinea, where he was wounded by two native spears. One of the spear-heads remained in his body for nine months, when it was extracted by Professor Cheyne at Edinburgh. The next few years saw him wandering and practising in the United States, the West Indies, Spain, Morocco, Paris, Australia, and ultimately in the Far East. His famous walk in 1882 across Australia, from Normanton to Victoria, a distance of 2,043 miles, was rivalled in 1894 by his 3,000-mile trip from Shanghai to Rangoon. In 1896 he travelled in Indo-China, and the following year he crossed Manchuria from Stretensk to Vladivostok. The part that he played in 1900 during the siege of the Legations in Peking is on record, as, too, are his services during the years that preceded the Boxer outbreak. His work in connection with the events which led up to the end of the Manchu Dynasty is within recent memory.

The Domiciliary Treatment of Tuberculosis.

THE Local Government Board have just issued an Order (No. 59,221) which they have made prescribing the manner of domiciliary treatment of insured persons suffering from tuberculosis, of which they approve for the purpose of Section 16 (1) (b) of the National Insurance Act, 1911. It is assumed that when the machinery for combating the disease in a district is complete, according to the recommend-

ations of the Departmental Committee on Tuberculosis, a dispensary with an expert consulting officer will be available in every area as part of the general public health organisation. The Order provides that the consulting officer means the consulting officer of a dispensary approved by the Board, who may be the medical officer of health for the district or any other medical practitioner. The actual treatment shall be carried out under the care and direction of a registered medical practitioner, subject to certain conditions, among which it is laid down that the patient is to be attended by such a medical practitioner at such intervals as may be necessary and that he shall receive from him instructions as to his mode of living, diet, rest and work, and as to precautions against re-infection. A card or sheet is set forth in an appended schedule upon which a continuous record of the patient's condition and progress is to be kept, in addition to the clinical history and particulars of the treatment employed. The medical practitioner is to report to the consulting officer from time to time, as specified, upon the progress of the patient and to give other details as required. The regulations are dated July 26th, 1912, and are applicable to England and Wales.

Eugenics.

THE wide realisation of our responsibility to posterity is a clear indication that selfishness and crude commercialism are far from dominating the public mind of to-day. It is true altruism to sacrifice present gain for the benefit of a future race. All thinking individuals are agreed that something should be done, but in methods of performance we are at variance. All hope for the future has its root in the past, and the first essential in making plans for future progress is a knowledge of the past. In some states of America, where money is always forthcoming, persons have been appointed whose duty is to visit the asylums for the insane, obtain the home addresses of a certain number of inmates and then visit the families of the latter. Working in conjunction with the local doctor, they then proceed to find out the histories of these families to as many generations as possible, paying particular attention to mental defects displayed by any of the progenitors. Some of these visitors are of high social position and find this occupation of the greatest interest. We remember asking one young and attractive lady if she had been able to discover anything of importance during the short time she had been engaged in this work. She replied that she had started on the case of an insane criminal who had been a prostitute, and on tracing back her family she had found that the female members of it had been prostitutes with criminal tendencies for five generations. Such retrospective human analysis seems to be the only rational manner of establishing a satisfactory system for work in the present. The American public seems to take the subject much more seriously than we do in this country, though the difficulties of tracing families in a new country is infinitely greater than in our own.

The "Medical Who's Who," 1912.

WHEN we received a prospectus, some few months ago, of a proposed new directory of medical men on novel lines, we then expressed the hope that it would be possible to make it a comprehensive list of every duly qualified practitioner. The "Medical Who's Who" for 1912 has now appeared as an attractive red volume about half the thickness of the ordinary "Who's Who." It is anything but a representative list, but, as the publishers, the London and Counties Press Association, Ltd., state

in their preface, all medical practitioners on the Register in Great Britain have been invited to furnish particulars of themselves, and it must be, therefore, due either to natural modesty or to apathy that the list is incomplete. Many names have, unfortunately, been received too late for insertion in the present issue, but it is hoped that the volume will be published in March of each year, and that the next one will be far more representative of the entire profession. The surnames are printed in heavy capital type, so that a given name can be turned up quickly, and the biographical details, so far as we have tested them, are plainly set forth, these being for the most part more intelligible than those often found in similar lists. If we may offer one criticism, we may suggest that no names of scientists, however distinguished, possessing no medical qualifications, should appear in the next edition. The book will prove to be, however, a valuable work of reference, and it deserves the cordial support of every member of the medical profession.

Obscene Advertisements.

At the last meeting of the Select Committee on quack medicines prior to the recess Lt.-Col. H. Everitt, one of the hon. secretaries to the White Cross League, gave evidence as to the advertisements of drugs and appliances for preventing conception, and for procuring miscarriage or abortion. He pointed out that a joint committee of both Houses of Parliament, appointed in 1908 to inquire into this question, had recommended legislation to prevent the sale and advertisements of these articles, and he urged that legislation should be no longer delayed. His society only referred to such matters as were outside the authority of the medical profession. They did not as laymen offer any opinion that affected the discretion of medical men in dealing with these matters. They recognised, for instance, that there were cases in which the life of a mother might be endangered by another birth. Col. Everitt strove to show that in the absence of such legislation as the Joint Committee of 1908 had recommended, the evils condemned continued and would go from bad to worse. He submitted copies of provincial and other papers to date containing obscene advertisements, and also circulars sent to women whose marriages and confinements were announced in the papers. In reply to questions, Col. Everitt submitted reports of twenty-one matrons of Rescue Homes on the use by, and effects upon, unmarried girls under their care; also evidence of the moral and physical injury consequent upon the knowledge by unmarried men and women of the use of preventives as a facility for illicit intercourse without detection. The enormous sums spent upon advertising are evidence of the extent to which these goods are employed. An equally large sum is annually expended upon the advertising of "ladies' remedies"—merely sham abortifacients. It is not only in inferior provincial prints that these shameful announcements appear. They are to be found in many papers that base themselves upon morality, piety and religion, and till lately were printed literally by the score in a London weekly paper circulating widely among working men and the lower classes.

PERSONAL.

WE deeply regret to announce the death, after a severe operation, of Mr. Arthur Trehern Norton, C.B., F.R.C.S., one of the proprietors of the MEDICAL PRESS AND CIRCULAR. An obituary notice will be found elsewhere in our columns.

H.M. THE KING visited the King Edward VII, Sanatorium at Midhurst last week, being received by Sir Frederick Treves (Chairman), Dr. P. Hartley, and other members of the Council and Resident Staff.

CAPT. M. W. FALKNER, R.A.M.C., has been appointed a Specialist in Operative Surgery.

DR. W. S. LAZARUS-BARLOW has been admitted to the Faculty of Medicine of the University of London.

DR. A. E. EVANS has been appointed Assistant Medical Officer of Health for the County of Flintshire.

DR. G. P. YULE, M.D., B.Sc. (Public Health), F.R.C.P.E., has been appointed County Medical Officer for Fifeshire.

DR. J. K. MOUAT, M.A.Oxon., M.B., Ch.B.Bristol, has been appointed Demonstrator in Pathology at the University of Bristol.

DR. F. HALL, M.B., Ch.B.Vict., D.P.H.Manch., has been appointed Assistant Medical Officer of Health of the Borough of Derby.

MR. L. A. DUNN, M.S., F.R.C.S., has been re-elected a Member of the Court of Examiners of the Royal College of Surgeons of England.

DR. C. M. HINDS HOWELL, M.D.Oxon., F.R.C.P., Lond., has been appointed Assistant Physician to Outpatients at the National Hospital, Queen's Square, W.C.

MR. E. F. FINCH, M.D., F.R.C.S., and Mr. P. A. Reckless, F.R.C.S., have been appointed Honorary Demonstrators of Anatomy in the University of Sheffield.

SIR HENRY MORRIS, Bart., F.R.C.S., has been appointed Visitor to the Examinations of the Egyptian Medical School for the examinations to be held in December.

DR. ROBERT N. PATON, Medical Officer of H.M. Prison, Wormwood Scrubs, has been appointed Governor of Holloway Gaol, in succession to Dr. James Scott, who has retired through ill-health.

MR. S. W. DAW, M.B., B.S., F.R.C.S., recently Resident Surgical Officer at the General Infirmary, has been appointed Surgical Tutor to Leeds University and Surgical Registrar to the Leeds General Infirmary.

DR. J. NEAL, formerly Secretary of the Birmingham General Practitioners' Union, has been appointed Deputy Medical Secretary to the British Medical Association in succession to Dr. Cox, the new Medical Secretary of the Association.

DR. W. AINSLIE HOLLIS, M.A., M.D., F.R.C.P., Consulting Physician to the Sussex County Hospital, Brighton, is the President-elect of the British Medical Association, the annual meeting of which will therefore take place in Brighton in 1913.

DR. H. E. ARMSTRONG, M.O.H. for Newcastle, is resigning that position after a service of 39 years, owing to advancing age. At a recent meeting of the Sanitary Committee of the Corporation the Chairman (Sir Henry Newton) paid a high tribute to the good work accomplished by Dr. Armstrong, and wished him long life and happiness in his retirement. In these sentiments we cordially desire to be allowed to share.

FRENCH CLINICAL LECTURE

ON

DIGESTIVE URÆMIA SIMULATING CANCER OF THE PYLORUS.

By M. CASTAIGNE, M.D.,

Professor at the Faculty of Medicine of Paris; Physician to the Beaujon Hospital.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—In dealing with patients suffering from digestive troubles you may sometimes find it very difficult to discover the underlying cause, the *primum movens*, of the gastro-intestinal disturbances. In some instances these may be due exclusively to concomitant chronic nephritis, and if this be overlooked you expose yourselves to serious errors of interpretation and treatment.

The relationship between renal affections and digestive troubles is far too complex to admit of its bearings being discussed within the limits of one lecture, and to-day I shall limit my remarks to a short chapter in this relationship. I shall discuss gastric symptoms simulating cancer of the stomach, which are under the dependence of a renal lesion, and I will relate to you various cases which will enable us to lay down the grand lines of diagnosis and treatment of these digestive manifestations, such treatment being diametrically opposed to what would be indicated in presence of a gastric neoplasm.

The first case is that of a woman, 42 years of age, who, for several months before admission to hospital, complained of loss of appetite, especially in respect of meat, and vomiting, which was watery in the morning and alimentary later in the day. When the vomit was particularly copious one could identify particles of food taken two or three days previously. Under these conditions she naturally became progressively emaciated.

One day after an attack of vomiting she passed blood *per rectum*, and this seemed to establish the diagnosis of malignant stenosis of the pylorus, so she was sent into hospital.

There the diagnosis was confirmed after a few days' observation, and in presence of the obstinate vomiting and the intestinal hæmorrhage, gastro-enterostomy was performed, but the patient died under chloroform.

I assisted at the post-mortem examination, which showed the absence of any gastric or intestinal cancer, revealing on the other hand the existence of chronic nephritis as shown by the fibrous state of both kidneys, one of which weighed three ounces and the other one an ounce and three-quarters. Histological examination showed them to be the seat of chronic interstitial nephritis. I have no doubt that these renal lesions were the cause of the symptoms which led to the diagnosis of gastric cancer. I shall not go further into this case because I did not see the patient until she was dead, and I content myself with placing you in possession of the main facts.

Case 2 was a very similar one, except that the patient was not operated upon, so that I was able to keep her under observation. She had been under treatment at home for troubles of the sort mentioned above, beginning with vague stomach trouble and hyperacidity (I shall refer later to the connection between acidity and renal disease). She had a good appetite for two or three months in spite of the digestive disturbance. Later on the big appetite and the acidity gave place to a dislike for all sorts of food, but especially for meat. Then

vomiting after meals supervened and became worse and worse, and the vomit often contained the remains of meals taken several days before.

At the St. Antoine Hospital they at once examined her gastric juice, when it was found not to contain any free hydrochloric acid, and there was a marked reduction in the combined acid, so that cancer of the stomach was suspected.

Then, too, the fæces were examined, and unmistakable traces of blood were found. These symptoms and the wasting led to a diagnosis of cancer, and she was sent into my wards.

At the first glance I had grave doubts as to the diagnosis, for, apart from the above symptoms, there were others pointing to hydruric nephritis. Arterial tension was between 28 and 30 in lieu of 15 to 17. This did not fit in with what we should expect in a patient with cancerous cachexia. The urine was extremely watery and contained very little solid matter. There was a faint trace of albumen. The methylene blue test showed that elimination was spread over four or five days, instead of about fifty hours. This patient then displayed marked chloride and urea retention, and the blood contained as much as three parts per thousand of urea instead of one-half part as does normal blood.

To clear matters up I had the stomach radiographed and the report was that the organ was the seat of atonic dilatation, but that nothing pointed to any pyloric obstruction. On the strength of these additional data I discarded the cancer hypothesis, and expressed an opinion in favour of the symptoms being wholly due to the kidney condition.

Not long after, in spite of strict dieting, the patient fell into a coma and passed away. The autopsy revealed typical chronic interstitial nephritis, with total absence of any disease affecting the stomach and intestine.

These two cases, one after the other, show that digestive disturbances of this kind may be simply due to chronic nephritis.

Now we come to a third case, which, though not verified by *post-mortem* examination, is nevertheless of great interest. It shows what excellent effects follow appropriate treatment and the unfortunate effects of a regimen which does not conform to the indications.

The patient was a man of 56, brought to hospital in a state of coma. His wife accompanied him and was able to afford us some useful information concerning his history. She told us that for some months past he had been suffering from sickness after food, with ever-increasing loss of flesh and physical depression. His doctor inclined to a diagnosis of cancer of the stomach, and having arrived at that conclusion he naturally placed the patient on a diet of very nutritive liquid or semi-solid food given in small quantities throughout the day—viz.: meat juice, powdered meat, eggs, purées, and so on. This highly nitrogenous food was well adapted for a patient with cancer of the stomach whose nutrition had to be maintained in spite of the vomiting.

According to his wife, the patient at first seemed to improve under this treatment—I omitted to mention that he was also having injections of normal saline solution. But as his nutrition seemed to improve the apathy increased and ultimately merged into coma.

The first thing that struck me was the very ammoniacal odour of the breath, testifying to uræmic intoxication. The pupils were widely dilated. Arterial tension was 25 and the heart was markedly hypertrophied with a cantering sound. Palpation of the abdomen failed to reveal any tumour or thickening.

Having diagnosed uræmia I at once performed venesection, withdrawing over a pint of blood, following this up with lumbar puncture. These two measures had for effect to withdraw a considerable quantity of the circulating toxins. Examination of the blood and cerebrospinal fluid showed them both to contain 1.5 parts of urea per thousand, so that there was obviously urea retention. Immediate improvement followed, and the patient tried to speak. I put him on water diet (three quarts of water containing 50 parts per 1,000 of glucose) and in three days his state had greatly improved. During these three days he had much diarrhœa and sickness, the former very foetid and ammoniacal, the which I was careful not to check since it also assisted in deparating the organism.

I had the stomach and intestine washed out, and in four or five days the vomiting and torpor had entirely disappeared. The patient was then clamouring for food, so he was put on a diet containing little nitrogen. His arterial tension diminished and he was able to go home, but, of course, he still had an enlarged heart with cantering rhythm and insufficient renal excretion with copious, slightly albuminous urine.

Here then we have a good example of gastric disturbance simulating the symptoms of gastric cancer and pyloric stenosis obviously due to chronic nephritis. Before quitting this case allow me to call your attention to the excellence of the results following treatment directed to his renal condition. This regimen remedied the disastrous effects of the previous treatment which had intensified the nitrogenous retention. Truly, as has been remarked, "nothing is as dangerous as logic when it starts on false premises."

In future, therefore, whenever you are dealing with a patient who presents the ordinary symptoms of cancer of the stomach, in the absence of obvious tumour look for signs of chronic nephritis. The presence of renal symptoms does not, of course, exclude the existence of cancer, but it opens up the question whether the symptoms in question are not due to the renal state. When no tumour is found and there is manifest renal mischief with chloride and urea retention, we are justified in suspecting uræmia and treating him accordingly.

The treatment will, of course, be based on the pathogenic data. The disturbances that accompany chronic nephritis are due to various forms of retention. In hydruric nephritis, as you are aware, the urine contains but a small fraction of the toxic substances of the organism, which therefore exist in excess in the humours and the blood serum. The presence of an excess of urea in the blood affords the most valuable information in respect of prognosis.

No doubt, alongside the urea, many other substances are retained. Dr. Chauffard, for instance, found that cholesterine was present in abundance in the serum in cases of chronic nephritis. In practice we usually look for urea. When this is present in amounts inferior to one part in a thousand the outlook is not unduly serious, but

above that amount, especially when it reaches two parts per thousand, the prognosis is grave, very grave.

The retention in the organism of urea and other toxic substances which are unable to pass through the renal filter explains the gastro-intestinal symptoms. The poisons that cannot be got rid of *via* the kidney are excreted *via* the stomach, whence the vomiting, the diarrhœa and the hæmorrhage from the stomach and intestine. The object of treatment, therefore, is to prevent the ingestion of substances that add to these retentions.

The treatment of the symptoms of uræmia will vary according to their severity. Slight initial accidents (loss of appetite and vomiting) call for strict diet. One or two days of water diet or lactose solution will usually abolish these symptoms.

When more marked or if they resist this simple treatment, we must wash out the stomach and suppress foods containing nitrogen.

When the vomiting and diarrhœa persist and the patient tends to become comatose, we must have recourse to energetic treatment: free bleeding, lumbar puncture, washing out the stomach and intestine, and in many cases an improvement will follow, though by the time the symptoms have attained this degree of severity the risk of a fatal termination is necessarily very great.

The moral which I wish you to draw from this lecture is that chronic nephritis may give rise to digestive troubles simulating cancer of the stomach. I insist on this in order that you may avoid an error of diagnosis which would entail a treatment disastrous to the patient.

NOTE.—A *Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Mayo Collier, M.S.Lond., F.R.C.S.Eng., late President of the British Laryngological, Rhinological and Otological Association; late Professor of Comparative Anatomy and Physiology at the Royal College of Surgeons, England. Subject: "Other Disorders of Impeded Respiration."*

ORIGINAL PAPERS.

PERSONAL EXPERIENCES IN THE SURGERY OF THE LARGE BOWEL. (a)

By F. T. PAUL, CH.M.LIV., F.R.C.S.ENG.,

Consulting Surgeon, Liverpool Royal Infirmary.

AFTER carefully thinking over the various branches of surgery in which it has been my lot to meet with fairly numerous cases, I came to the conclusion that I would offer you my experiences in the surgery of the large bowel. This would be too wide a subject for a single address if one proposed to travel over the whole range of surgical troubles in this region; but by limiting my remarks to those procedures in which some advance has been made during recent years, and of which I have had a fair personal experience, I hope to keep this address within reasonable limits. This will restrict me to the consideration of cases in which the following operations have been employed: (1) colotomy; (2) short-circuiting; (3) colectomy; and (4) excision of the rectum.

These operations are needed to meet very different pathological conditions, though most of them ultimately present the clinical feature of obstruction. One alone, however, cancer, accounts for more than all the rest put together, and therefore the greater part of my remarks will be concerned with

(a) Abstract of the Address in Surgery delivered at the Annual Meeting of the British Medical Association, July, 1912.

cases of malignant disease—a disease which in the alimentary canal usually first threatens life by mechanically interfering with its functions.

In the first place I am quite convinced that cancer of the bowel may undergo spontaneous cure. It is much more easy to make a statement like this than to prove it, and I doubt if I can offer any really convincing proof. The following are the grounds on which the assertion rests:—

1. For over 30 years I have been removing these growths and submitting them to personal microscopic investigation. I am, therefore, very familiar with their nature and appearance.
2. Many cases having the minute structure of cancer have not recurred, though known to have been removed with an insufficient margin of safety.
3. Malignant disease of the bowel is very rarely removed during the early stage, yet the percentage of cures is remarkably good.
4. The duration of life after colotomy for inoperable cancer of the bowel is often prolonged compared with that in other inoperable cancer cases, whilst a proportion of the cases seen, handled, and passed as malignant get well and the tumour disappears.

TYPES OF INTESTINAL CANCER.

The three varieties of carcinoma are:

1. The large soft fungating "encephaloid" type.
2. The small hard "scirrhus" type.
3. The infiltrating "colloid" type.

All may be said to be primarily columnar-celled growths originating in the intestinal glands, and all ulcerate; but they follow different paths of evolution, and attain different degrees of malignancy which it is important to recognise.

The scirrhus variety is always unmistakable. It produces the hard ring stricture of the bowel, and is more common than colloid cancer, but much less frequent than the soft fungating type. This latter may usually be as easily distinguished from the colloid form of growth by the following characters: It is softer to the touch. There is a good deal of fungating growth within the bowel, but generally not much solid infiltration of the bowel wall. There are usually numerous large soft glands in the neighbouring mesentery, which are septic and not malignant. In colloid cancer, on the other hand, there is a hard-edged ulcer with no fungation. There is dense hard infiltration of the bowel wall, often attaining a thickness of from one to two inches, and giving it a solid feel. The glands, if infected, are not soft, but hard and glistening.

Misconceptions exist regarding the nature of these different tumours. In the first place, some seem to forget that "scirrhus" and "encephaloid" are merely terms of clinical or macroscopic significance, convenient when properly used, but otherwise very misleading. Almost any histological variety of cancer may take on either character without change of cell type. Even in the breast scirrhus does not imply acinous growth, as either round-celled acinous cancer or columnar-celled duct cancer may present this clinical feature. Some speak and write as though the term "scirrhus" was equivalent to mammary cancer, and consequently that a scirrhus type of cancer in the bowel means a cancer histologically resembling breast cancer; whereas no form of bowel cancer could be identical with a breast growth any more than bowel and mammary tissue could be identical. They may, and do, present similar clinical characteristics, and a hard ring stricture of the colon resembles a breast scirrhus, or a thyroid scirrhus, or any other scirrhus in its hardness, in its tendency to cell degeneration, to slow but inveterate growth,

to lymphatic infection, and difficulty in complete eradication.

The really important misconception, however, concerns the relative malignancy of the three varieties of cancer. Usually the big, fungating, encephaloid type of growth is regarded as the most malignant; the colloid as being intermediate, and the scirrhus, or ring stricture, as the most benign. This arrangement is entirely wrong and out of accord with clinical experience. The colloid is the most malignant type, the ring stricture comes next, and the fungating type is the best—it being one of the least malignant kinds of cancer met with in the body.

DEGREES OF MALIGNANCY.

It is a clinical fact of considerable importance, to which I have often referred at our local medical society, that the up-growing forms of cancer are essentially less malignant than the down-growing, ulcerating, and shrinking types. Take as examples, fungating epithelioma of a warty or cauliflower character on the tongue, larynx, or skin, and compare with much smaller but more infiltrating and ulcerating growths in the same positions. Surely our operation results have always been better, far better, in the former than the latter. Again, in breast cases, take the case of a soft encephaloid-looking duct cancer, and compare with a small infiltrating, shrinking scirrhus. The duct cancer, notwithstanding its malignant appearance, will often yield an operation cure, whilst the little simple-looking scirrhus turns up again in skin, glands, or internal organs. The duct cancer belongs to the up-growing papillomatous class, whilst the scirrhus infiltrates, degenerates and ulcerates. Papillomatous and villous growths are on the border line between innocence and malignancy. On the skin they are for the most part quite innocent. In the mouth or larynx we regard them with more suspicion. In the bladder they show a still worse tendency, and in the bowel I doubt if they can be called innocent at all. The familiar rectal polypus is adenomatous or glandular, rather than warty; but there are true papillomata apart from the polypi, and it is these which should always be regarded with grave suspicion.

SARCOMA OF THE BOWEL.

Sarcoma of the large bowel in my practice has been very rare. Some years ago I had a case of small round-celled sarcoma of the rectum in a woman, aged 50, at the Royal Infirmary. It formed a spindle-shaped tumour of the middle third, strictureing the bowel without ulceration, and was recognisable as a sarcoma before microscopical examination. It was excised, but recurred, and the recurrence was fatal within a year. Recently, in private practice, I met with one of those rare examples of melanotic sarcoma of the rectum. It formed a small fungating tumour low down on the posterior wall in a male aged 70. He was not a suitable subject for a radical operation, and did not live long, for the growth proved to be very malignant, and was rapidly and widely disseminated. I do not refer to one or two cases of congenital malignant growth that I have seen in connection with the rectum, as they have no bearing on the matter in hand.

INDICATIONS FOR OPERATION.

If the growth be of the fungating type, recognised by its softness, bulk, situation, character of gland infection, etc., the surgeon would, on the one hand, feel justified in removing the tumour without necessarily interfering with any tissue much beyond the visibly affected area; or, on the other

hand, if the risk to life seemed too great to allow of this being done, he would be encouraged to hope for a reasonably long period of relief by short-circuiting or colotomy. If the tumour prove to be massive and solid, and especially if there be evident glistening gland or peritoneal infection, or if the growth be in the rectum and can be felt as an abrupt hard-edged ulcer without fungation, then the case is one of colloid cancer, and the outlook would be recognised as discouraging. When a wide and thorough removal appeared warranted it might be undertaken; but as the prospect is never good in colloid cancer, either for excision or temporary measures, less risks to life should be accepted. In the case of ring strictures, always easily recognisable, the indication is to excise more widely than one used to think necessary, and to remember that it is in this type of growth we have the best reasons for following up the path of lymphatic infection. These rules for my guidance have come to me gradually as the result of practical experience.

The first great line of demarcation in the clinical arrangement of these cases is the presence or absence of complete obstruction at the time they come under a surgeon's observation. In all my earlier experiences, say from 1878 to 1890 or later, complete obstruction with faecal vomiting and meteorism were regarded as necessary preliminaries to an application for surgical aid, and one soon found that any attempt to relieve the obstruction which did not provide for an immediate external escape of the locked up contents of the bowel was doomed to failure. So constantly fatal were all operations for intestinal obstruction in those days through delay that one thought very little of the objections to an artificial anus. It was a great event to save life at any cost. Nor should any such feeling of objection encourage us now to risk life for the sake of at once accomplishing a neat and clean surgical procedure. Even short-circuiting seems often to fail when colotomy is at once successful, and I feel sure that whenever there is complete obstruction in the colon a preliminary colotomy is by far the safest course in all those cases in which any form of internal strangulation can be excluded. The one class of case in which I should always wish to make an exception whenever possible is when the obstruction is actually at the ileo-caecal valve, and it is necessary to open the small bowel. There are such decided objections to a faecal fistula connected with the small intestine, and usually such favourable prospects for short-circuiting in this situation, that the additional immediate risk may be accepted unless paresis and collapse have already supervened, when an artificial anus is imperative.

DIAGNOSIS OF BOWEL CANCER.

Unfortunately we are still without means for recognising cancer of the bowel in its really early stages. In fact, it sets up no symptoms at this period of its growth which would lead a patient to consult his doctor, except when low down in the rectum. Here it excites irritability, and attracts attention by the presence of blood and mucus, and so often allows an early diagnosis; but higher up we have almost invariably to wait until the growth has begun to impede the passage of faeces before the patient is sufficiently alarmed to seek advice. Large ulcers without marked obstruction are chiefly characterised by intestinal toxæmia, with elevation of the temperature, flatulent dyspepsia, loss of flesh, irregular colic with constipation or diarrhoea and mucus and blood in the motions—visible when the growth is low down, occult when higher up. A tumour may frequently be felt. The ring stricture usually causes less disturbance to the

general health, but more colic and more obstruction. X-ray screen view of the behaviour of a bismuth meal is useful if its limitations are recognised. It may inform us as to the site and the amount of constriction, though in regard to the latter atony or tonicity of the bowel must be taken into consideration. In no circumstances can it indicate either the extent or the malignancy of the growth, nor can the ready passage of a bismuth meal be regarded as a contra-indication to operation. If the disease is within the reach of the sigmoidoscope this treatment may be of considerable assistance in the diagnosis of growths situated in the pelvic colon, where they frequently escape touch when examined either by the rectum or the abdomen.

OPERATIVE METHODS.

Right lumbar colotomy is now shorn of its terrors by greater familiarity with abdominal operations. When the colon is distended it is easily found on either side. When not distended the peritoneal cavity may, if necessary, be opened for exploration and closed again with but slight detriment to the patient. I always suture the bowel to the skin, as in iliac colotomy, and very rarely attempt to make a spur, since the lumbar operation is almost invariably a temporary measure to be done away with as soon as it safely can be. The disability resulting from an iliac colotomy is not nearly so great as is so often assumed. If it were, the operation would be robbed of three-fourths of its value. When a satisfactory surgical result has been obtained it only needs a little pluck and a desire to make the best of a disadvantage for any ordinary patient to continue to lead a useful life. I have known a doctor to continue the full work of a general practitioner for years, a ship steward to follow his avocation on a big Cunarder, and a lady with this disability for life to continue to make a charming hostess and to be the brightest member of her family. With these and many similar examples within my experience I cannot sympathise with the weak-spirited individual who sinks under the misfortune of such a personal discomfort.

Short-circuiting is a more pleasant operation for the patient than colotomy, and for this reason may replace it whenever it is feasible to do so, but the latter will always be necessary for inoperable rectal cancer, for dangerous obstruction, and for colitis, and some other ulcerative affectations of the colon, so that the former really only comes under consideration in a small proportion of the whole number of cases.

However good the results of short-circuiting or colotomy may be, we must always wish to excise a malignant tumour of the bowel whenever circumstances permit, and I propose now to deal with the operations planned for the removal of such growths, taking first those situated in the colon, and then those in the rectum. The caecum and the sigmoid are the most favourable, and fortunately the most frequent situations for malignant tumours of the colon. The caecal operation is certainly the more extensive of the two, and I used to prefer the sigmoid site, but on the whole I think the caecal cases have done the best, chiefly in the way of the cure being more permanent. Increasing experience has encouraged me to undertake the major operation in more cases of cancer of the colon, and in less cases of cancer of the rectum.

RECTAL SURGERY.

There still remains the lowest portion of the large bowel to be dealt with, the rectum, and I do not propose to ask your attention now to any conditions of this part, except those which call for excision. One may sometimes attempt

a resection of the rectum for other affections than malignant growths, but too rarely for such cases to have any influence upon our general method of operating. I have, indeed, excised syphilitic strictures, but it is long ago, and now it seems to me that such a serious operation as resection should be reserved for those cases in which the disease will prove fatal if not removed, the rest, if needing it, being treated by iliac colotomy. I have already expressed the view that a well-planned colotomy is not inconsistent with health and reasonable comfort or with the pursuit of ordinary avocations when a little consideration is extended to the person who has had to suffer this misfortune. If this were more generally admitted some lives—perhaps many—that are risked and lost would be saved, and many that struggle on to the end in misery would have some comfortable days in store for them. All cases of advanced cancer of the rectum, incurable fibrous stricture from syphilis or other cause, some recto-vesical fistule, and some tuberculous and other ulcerations should be treated by colotomy.

Does a preliminary colotomy lessen the risk of excision? Yes, it does. I think this cannot be doubted, and if so one should give great weight to the fact in all the more serious cases.

Operations for cancer of the rectum are on the whole less favourable than those on the colon. Contrasting the two I should say in excision of the rectum we have more hæmorrhage and shock, usually a more difficult operation, less freedom in removal, a larger and more serious wound to heal and a more malignant type of cancer to deal with. On the whole the results of excision of the rectum are good, but there are reasons why we should expect a slightly higher primary death-rate, and a greater probability of recurrence than in the case of colectomy.

THE PRE-OPERATIVE DIAGNOSIS OF APPENDICITIS: A DEMONSTRATION OF A DORSAL METHOD OF EXAMINATION. (a)

By WILLIAM EWART, M.D.CANTAB., F.R.C.P.,
Consulting Physician, St. George's Hospital, &c.

This method, which provides *normal* "standard" physical signs for the healthy state, and also for the completeness of the post-operative result, and *abnormal* "localising physical signs" for the retro-cæcal lesions, and for some of the "central" and of the "pelvic" lesions, whereas abdominal palpation can reach only the "anterior lesions," adds considerably to the range of our *objective pre-operative diagnosis* (both positive and negative) by demonstrable physical signs. It is simple and rapid, painless and harmless, and, within its own competence, singularly accurate and reliable. The *practical conclusions* claimed to have been established by an extensive clinical investigation, and by confirmatory *surgical test cases* are as follows:—

It is the only available test (1) for the normality of appendicial district; and (2) for the post-operative results of surgical interference, whether completely successful, or sometimes calling for a secondary operation. (3) It is unique in supplying direct localising evidence in the large group of *retrocæcal lesions*, which are inaccessible to pre-operative diagnosis, even by X-rays; often also in the *pelvic*, and sometimes in the *central lesions*. (4) Except in the "anterior" group of appendicitis, hitherto the only group "of physical signs," it is the

only *objective evidence* for deciding at once the *urgency* of operations which at present are undertaken for "existing symptoms"; and (in their absence) the expediency of operations now justified by nothing else than the plea of "safety." (5) It has a direct bearing in all cases upon the *modus operandi*, not only in the deep-seated and posterior ones; but particularly in the *anterior ones* (re possible "extension," or "no extension" backwards), where it is capable of settling any doubt as to the management of the retrocæcal field.

To sum up: (6) It is indispensable for *certificates* of appendicial soundness, and of a perfectly normal result after operation; (7) for the *decision as to an operation* in all sub-acute, latent or doubtful cases; and (8) for the most satisfactory operative management of severe cases. With exceptional reservations a dorsal examination should never be omitted as an essential part of the routine of surgical pre-operative diagnosis.

The demonstration was illustrated by diagrams and by a large number of clinical tracings, taken before and after operation, which bear out these conclusions.

ON THE NECESSITY FOR A NECROPSY IN EVERY CASE OF DEATH. (a)

By J. C. MCWALTER, M.A., M.D., LL.B.,
F.R.F.P. AND S.GLAS.

WHAT do people die of? The street arab will scoffingly say—"Of shortness of breath." He is much nearer the truth than fifty per cent. of medical certificates of "causes of death." We are touchingly told, in Dr. Kirkpatrick's admirable "History of the Trinity College Medical School," that at one time the King's Professors of Medicine strongly objected to Macartney, the Professor of Anatomy, performing necropsies on their patients—feeling, doubtless, says our author, that it was not consonant either with their reputation or their dignity to have their diagnoses reversed by the *post-mortem* disclosures of an unsympathetic colleague.

Even on the Continent, and where the services of the most skilled hospital physicians were availed of, I have been informed that in a series of cases the diagnosis was not right even once as proved by the *post-mortem* finding.

Our American brethren have a sceptical query—"What is rheumatism?" The answer is—"Well, in ninety per cent. of the cases—certainly not rheumatism." When we ask, "What did the patient die of?" the answer in ninety per cent. of cases should be—"Well, certainly not of the certified cause of death."

Sickness and death have suddenly become a live question. The State is stepping in. Hitherto it only meddled, in a half-hearted, tentative sort of way, in what was called preventive medicine. This was taken to mean zymotic diseases—which do not account, at the most, for more than 3 to 4 per cent. of all deaths.

Now the State stands forth to tackle the great problem, not only of death, but also of sickness and unfitness for work. A certain statesman has decided that half the poverty is due to sickness, and he is prepared to spend 20 millions a year in dealing with sickness.

The great problems of sickness and death depend on Vital Statistics. Immense sums are spent to have these statistics prepared. But are they any real use? I suggest not. How should any Vital Statistics which were intended to serve any scientific purpose be prepared? Obviously from causes of

(a) Abstract of paper read at the Surgical Section, B.M.A. Annual Meeting, Liverpool.

(a) Paper read at the Berlin Congress of the Royal Institute of Public Health, July 26th, 1912.

death verified by necropsies performed by competent men. How are they really prepared? Except in cases of violence necropsies are not performed in one per cent. of the cases of death, and the alleged "cause" is merely a wild guess or a conventional statement by a practitioner who is not even required to state, or to know, that the patient is dead at all.

As an example of prevailing ignorance let me quote my own case. I find that I have certified considerably over a thousand "causes of death." Out of this thousand there were not ten cases verified by *post-mortem* examination. Not in 95 per cent. of the cases did I see the patient after death. It is quite possible that in 60 or 70 per cent. of the cases the "cause of death" was either erroneous or so vague as to be scientifically worthless.

Now, the Registrar General's Returns are made up of my thousand cases, and of the thousand cases of other practitioners who are probably not less ignorant than myself. Surely it is a savage farce to draw conclusions from data such as these?

In what percentage of cases are proper *post-mortem* examinations made? No definite figures are available, but the number appears to be less than one per cent.

I find that out of about 100,000 deaths there are about 1,600 from violence. These comprise the greater part of those which are the subject of coroners' inquests. Thus the very cases in which *post-mortem* examinations are actually held are those from which the least information of any value is derivable—for we do not want to know the cause of death where a man is killed by violence, but when he dies from disease.

Out of your 100,000 deaths there will be about 1,500 in lunatic asylums. A certain number of these will be the subject of necropsies, and we must confess that the yield of information afforded by them is not great; but really if a man be twenty or thirty years in an asylum it does not so much matter what he died of.

Deaths in workhouses and workhouse hospitals comprise a large proportion of every 100,000 deaths. In Ireland they would be about 10,500. The number of necropsies on these is very small indeed.

Let us look at the question in another way. There die in Great Britain about a million people every year. The State proposes to spend some £25,000,000 a year in preventing sickness and death. There are also actively engaged in warding off death some 30,000 doctors, who, at an average salary of £300 a year, receive some £9,000,000 annually for their services. And their endeavours are largely futile, and all the money spent must be largely wasted. Why? Because really we are working in the dark. We don't know what people die of. Our opinions as to the disease and the cause of death may be of the most fallacious and misinformed type possible; but instead of correcting them by a *post-mortem* inspection, we are allowed to embalm them in the Registrar General's Reports, and so lead others into the same morass of ignorance.

Death, we are told, comes in through the brain, the lungs, or the heart. It may well be so. If we continue to ascribe death to cardiac failure, dyspnoea, or convulsions, we may, perhaps, be right; but can any man suggest that we shall ever improve the science of medicine, or do anything really helpful to the State so long as we are satisfied with these vague generalities.

Further, I submit that we are led even further astray by those authorities who ought to be infallible. Glance at the Registrar General's "New

List of Causes of Death." You are begged not to state that your patient died of carbuncle, but you may certify he died of eczema. You are implored not to say that he died of peritonitis, but you may attribute his demise to an ulcer. You must not say a child died from gastric catarrh, but you can state that its fatal trouble was varicose veins. I doubt if caries pure and simple ever killed anyone, but I find I can certify that it did, whereas I cannot say that "heart disease" pure and simple killed a man. For the life of me I cannot see why a man should be permitted to state that "arthritis" was a cause of death, whilst he is warned off attributing it to "brain tumour." Why under heaven should abortion be put as a cause of death? We know, of course, that death will often follow it—just as it may follow the scratch of a pin, but surely it is not the cause—or, if it be, "childbirth" is a far commoner cause, and it is not recognised as all. What, then, is the sense of ascribing death, generically, to "Diseases of the Nose," "Diseases of the Eye"? To cap the climax you are exhorted to state, by the mystic letters P.M., when the cause of death has been verified by *post-mortem*, and when you write to the Registrar General for the number of deaths verified by *post-mortem* you find that no such list is available.

It is obvious that the healing art can never advance until we foresee that every blunder of ours will be made manifest at the *post-mortem* examination. It is as clear as the sun that medical treatment is mere blind muddling in the dark when we never know anything about our patient except that he died.

On the other hand, an immense mound of prejudice must be overcome before the public will submit to universal necropsies. It must be shown that the practice will put an end to the common horror of premature burial. It will gradually be seen that it protects every man from poisoning or foul play, as well as incompetence. We must realise that each of us ought to be proud if by his death he contributes something to a knowledge which may serve posterity. It cannot come to pass in a day, perhaps not even in a generation; but I suggest that if the Berlin Congress of the Royal Institute of Public Health marks the first public insistence on the necessity for necropsies it will have done good work for mankind.

DEEP PETRISSAGE OF THE ABDOMEN AS AN AID TO THE DIAGNOSIS OF TAPEWORM.

By RICHARD J. CYRIAX, M.R.C.S., L.R.C.P.
LOND., L.M.

As a general rule, a patient is not suspected of having a tapeworm until segments are passed in the stools, which is naturally pathognomonic of the condition, any abdominal symptoms presented by an unsuspected case being ascribed (in the lack of further evidence) to dyspepsia; but there are sometimes sufficient grounds for believing that a tapeworm is present, even when no segments have been passed. In such a case the problem of diagnosis is sometimes a difficult one, unless the same measures are resorted to as when a tapeworm is known definitely to be present—namely, dieting and the administration of salines, followed by an anthelmintic and a brisk cathartic; thus the diagnosis and treatment are often combined. Many authorities hold, however, that these procedures are unjustifiable except in undoubted cases. The administration of a purgative alone, without an anthelmintic, is advised by some authors, the

motions being subsequently examined for segments and ova; but a purge by itself is apparently not always successful in bringing away proglottides, and examining the fæces for ova is a very unpleasant process. In any case, diagnosis by means of anthelmintics involves considerable discomfort and annoyance to the patient, temporarily interrupting the daily routine of work in a manner particularly harassing to busy people. When a diagnosis of tapeworm has been confirmed, drastic action of the nature referred to of course becomes necessary, but sometimes cases of unconfirmed suspicion occur, in which smart purgatives even by themselves are contraindicated and not to be made use of unless necessary—e.g., such conditions as severe hæmorrhoids.

The object of this paper is to direct attention (it is believed for the first time) to deep pétrissage of the abdomen as an aid to the diagnosis of tapeworm. Cases in which the presence of a tapeworm is actually suspected without any supposed segments having been passed are indeed comparatively rare, but they do occur, and require elucidation and cure; and beyond this, the author himself has seen and further heard of several cases in which the parasites' presence was unsuspected until the pétrissage caused proglottides to appear in the stools, cases in which this occurrence does not seem to have been of the nature of a coincidence. In one of these cases, the patient had taken all kinds of purgatives for the relief of constipation without passing any segments; I herewith quote such portions of the notes as bear essentially upon the point under discussion.

CASE. Mr. A. B., business man, æt. 50, came under observation September 12th, 1910. He complained of chronic constipation of about twenty years' standing, flatulence, and an "uneasy feeling" in the abdomen, referred to the umbilical region. He could not recall how long the latter condition had lasted, but it had been present for a long time. He had continually to resort to laxatives and enemas in order to produce a motion, and had tried all sorts of medicines for the relief of constipation. His appetite was good. Examination of the abdomen was negative except for some tenderness over the descending and iliac colon. His tongue was slightly furred.

It was thought at first that the subjective sensation in the abdomen was due to the constipation. The patient was advised to stop all purgatives and to undergo a course of mechanotherapeutical treatment, consisting of deep pétrissage of the abdomen and active exercises directed toward strengthening the muscles of the abdominal wall.

After three treatments the patient passed one segment of a tapeworm independently of a motion. After another treatment he passed about twenty segments, which, on examination, appeared to be derived from a *Tænia solium*.

The patient was advised a light diet for twenty-four hours, and received two Seidlitz powders during the day. The following morning he took a drachm and a half of liquid extract of male fern fasting, followed two hours later by an ounce and a half of castor oil mixture. About three yards of worm were passed. The head was not found, but as the segments could not be examined immediately and had to be brought by the patient for the purpose, it is quite likely that he had overlooked the head and thrown it away with the remainder of the motions.

The umbilical sensation of uneasiness now became very much less, and had disappeared entirely ten days later. Mechanotherapeutical treatment, as

outlined above, had meanwhile been continued, ceasing October 28th, 1910.

I have seen this same patient at intervals since the latter date, the last time being November 22nd, 1911. He said that although he had very carefully watched his motions for proglottides, and had occasionally repeated the anthelmintic treatment, he had never passed any segments.

PÉTRISSAGE.

By deep abdominal pétrissage is meant a series of circular movements executed in the direction of the large intestine with sufficient energy to cause a thorough kneading of the abdominal contents. In carrying it out, it is essential that the abdominal parietes and the fingers of the operator move as one over the underlying viscera, otherwise the process is resolved into a mere superficial effleurage, which hardly influences the viscera. It is not necessary for the pétrissage to be executed very hard in order to achieve the desired end; and unless the technique is defective, it should cause no pain. When properly performed it presumably effects the dislodging of the proglottides in two ways—by promoting peristalsis and by mechanically separating segments of the distal end of the parasite by tearing through their attachments. Of these two actions, the latter is probably by far the most important. The increased peristalsis seems to act only as an adjuvant in expelling the separated segments, and probably no intensity of it can actually dislodge the head of the worm; nor does it seem possible to reach the point of achieving this by the merely mechanical effect of the pétrissage. The latter is, therefore, only a means of diagnosis as regards tapeworm infection, and cannot replace the usual curative treatment.

CONCLUSIONS.

The advantages maintained for this method of establishing a diagnosis of tapeworm are briefly as follows:

1. It is entirely harmless, and reveals worms in some cases in which purgatives alone have apparently not been successful.
2. It does not interfere with the patient's regular work, and causes no discomfort worth mentioning. As a general rule, only about three or four applications of deep abdominal pétrissage, each of fifteen minutes' duration, are required to establish a definite diagnosis.
3. It abolishes the unnecessary administration of purgatives, alone or in combination with anthelmintics, in cases when they are contraindicated.
4. It is apparently uniformly successful. The author's brother, Dr. Edgar F. Cyriax, has kindly allowed it to be stated here that he has carried out at least 30,000 deep pétrissage treatments of the abdomen for many varieties of complaints, and that no case in his experience has yet occurred in which a patient was discovered to have a tapeworm within such a period of time after the conclusion of the treatment as would leave no doubt that the parasite had been present during it, and many of the patients were under observation for a long time. Moreover, several cases have occurred in this series in which, during the course of treatment for other complaints, the presence of a tapeworm was first revealed through such deep pétrissage of the abdomen causing proglottides to be passed in the stools, no other symptoms having previously manifested themselves that could justify a suspicion of the actual fact.

DR. G. E. MORRISON, M.B., C.M. Edin., the well-known correspondent of *The Times* in Peking since 1897, has been appointed Political Adviser to the President of the Chinese Republic.

SOME MEDICAL ASPECTS OF EUGENICS. (a)

By A. F. TREGOLD, L.R.C.P.LOND., M.R.C.S.ENG.

(Concluded from page 112.)

In the examination of the family history, which is, of course, the essential point upon which our advice regarding marriage must be based, it is of the utmost necessity to inquire into the condition of the collateral as well as the direct antecedents. As in hæmophilia, the taint may be transmitted by a person not himself affected, and a person may be apparently normal, but, if he comes of a markedly abnormal stock, may still pass on the defect. Of this I have seen very many examples, and the only safe rule is to ascertain the condition of every member of the family, collateral and direct, for three generations. When this is done it will be found that cases fall into three groups. *Firstly*, there are individuals belonging to a stock of which the members are healthy, have lived to a good age, and are in every way a credit to the nation. Such should be strongly advised to marry; indeed, I hold it to be the duty of the State to encourage their propagation in every way, even by the substantial endowment of their children if they are in poor circumstances. *Secondly*, there are those who come of a markedly morbid stock containing members who have been insane, epileptic, criminal, profligate, or otherwise socially incompetent. Not only should the marriage of such be forbidden by the physician, but it should be prevented by the State. *Thirdly*, there is an intermediate group in which there may be a slight neurotic tendency or indication of some diathesis which is not of a particularly disabling character, or of which we do not yet fully understand the racial consequences. In the present state of our knowledge these must be given the benefit of the doubt; at the same time, however, we should strongly advise against marriage with a person of similar tendencies. I may here remark that an excellent schedule for recording family histories has recently been published by the Eugenics Education Society, which, if generally adopted, would be of the greatest value in supplying us with the necessary data upon which to form our conclusions.

In addition to the investigation of the family history, the individual himself should be medically examined before any opinion is given. Apart from the presence of inherited taint, it is my opinion that certain bodily states of the individual may so impair the germ plasma as to produce injurious effects upon the offspring. What is commonly called hereditary syphilis is, of course, not hereditary at all, but acquired *in utero*; but there are reasons for thinking that imperfectly treated syphilis may lead to a real germinal impairment which is transmissible. The same is true of plumbism, and, as has been shown by recent microscopical work, also of chronic alcoholism. I believe that the time is coming when the State will be compelled to assert its authority on this question of marriage, and I have already advocated the granting of licences based upon the medical condition of the individual and the eugenic fitness of his family record. In the meantime, it behoves us to be prepared to give advice to the ever-increasing number of our patients who appeal to us on this matter.

So far, I have spoken as if marriage and propagation were synonymous terms. But they are not; marriage has a twofold object—the affording of a congenial and helpful companionship, which is in itself a blessing of no mean value, and the procreation of children. The question arises, where the only bar to marriage consists in the undesirability of propagation, is it possible to obtain the advantages of a beneficial companionship without this evil result? We know that methods are made use of to secure this end, but such methods are not always reliable; they involve considerable inconvenience, and they have even been denounced as dangerous. This brings me to the next point I wish to consider—namely, that of sterilisation.

STERILISATION.

It is sometimes urged that such a procedure—or, indeed, any artificial restriction of propagation except that of abstinence from intercourse—is immoral. I fully admit that many methods which are now in vogue may, and frequently do, conduce to immorality and illicit intercourse; but I cannot agree that they are immoral in themselves. I regard the person who brings into the world diseased and degenerate children, whose existence is often a lifelong misery to themselves as well as a source of injury to the State, to be far more guilty of immorality than the one who refrains from such procreation, even by the adoption of artificial methods. It will, of course, be understood that I am only referring to artificial restriction on medical or eugenic grounds. The adoption of such a practice from motives of selfishness, luxury, and the desire to shirk parental and civic responsibility cannot be too strongly condemned.

It is undeniable that the question of sterilisation produces a very considerable feeling of repugnance in the minds of many people. I believe that much of this is due to ignorance regarding what is really meant. Sterilisation is frequently spoken of as mutilation, and there are even many medical men who look upon it as implying castration or ovariectomy. The complete sexual impotence and the pronounced alteration in the whole being which result from such operations fully account for the natural feeling of abhorrence. Fortunately, there is now no need for such barbarous methods if the object is merely to prevent propagation, although I think that even castration has its use and is attended with considerable advantages in certain types of cases. Sterilisation consists merely in ligation of the Fallopian tube or *vas deferens*. The operation is perfectly simple; it has now been performed for several years and upon hundreds of cases in America; it does not result in any loss of sexual power or desire, or any interference with secondary sexual characters. Its sole effect is to render the individual incapable of propagating his or her species.

There can be little doubt that some of the objection which is felt to this proposal is attributable to the intemperate and indiscriminate manner in which it has been advocated by injudicious persons. It has been vaunted as a national panacea, and it has even been suggested that the insane, the feeble-minded, imbecile and idiot, the criminal and the chronic pauper may safely be turned loose upon society once they have been sterilised. This view is, of course, absurd. Sterilisation will prevent these persons propagating, but it will not make a mental defective competent, a pauper independent, or a criminal moral. In very many cases segregation and supervision will still be called for on account of personal traits. Nevertheless, I believe that it is a most valuable measure in suitable cases, and one which is certainly worthy of our careful consideration.

The question is, what are the suitable cases? I entertain no doubt that there are many individuals who should be compulsorily sterilised. For instance, of the number of patients annually certified as insane, about one-third of those in asylums and one-half of those in private care are discharged recovered, partially recovered, or unimproved. About three-fourths of the women and nine-tenths of the men thus discharged are of the reproductive age, and there is not the slightest doubt that very many of them do reproduce. I do not suggest that all these discharged lunatics come of such a pronounced neuropathic stock that their offspring is degenerate, but I am quite certain that this is the case in the majority, and that their liberation is attended with a very considerable menace to the nation and to posterity. I do not know that the ordinary sane man in the street quite thinks that they are liberated for the express purpose of counteracting the diminishing birth-rate, but he certainly regards it as an extraordinarily unbusiness-like, even absurd procedure. And it is absurd; but the authorities are powerless in the matter. Asylums are not institutions for the carrying out of restrictive eugenics; they are for the treatment of the insane, and as soon as a patient recovers his sanity his further

(a) Delivered at the Medical Graduates' College and Polyclinic, March 6th, 1912.

detention is illegal; as the law now stands he *must* be discharged. It is for cases of this kind, where the insanity is clearly due to morbid heredity, that compulsory sterilisation is not merely justifiable, but a national necessity. In the same category I would include those epileptics and feeble-minded for whom permanent segregation and close supervision is not necessary, and where the only danger consists in their propagation.

I am afraid that compulsory sterilisation is still a long way off, but the eugenic movement has now spread to such an extent that many persons exist who are willing to submit to the operation, and who are coming to us for assistance. It is from this point of view that I desire to say a few words.

And, first of all, it is, perhaps, necessary to remark that there is no legal bar to the performance of this operation. Doubtless, if it were found to be made use of for improper purposes, and solely to shirk the inconvenience and responsibility of parenthood, it would become necessary to prohibit it by severe penalties, as in the case of abortion; but at present it is perfectly legal, and in proper circumstances I believe that the medical man is not only quite justified in acceding to a request to perform the operation, but that circumstances occur in which he is justified in suggesting and recommending it. There are, however, two points which must be borne in mind. For his own safety the surgeon should require a written request from his patient expressly stating that he or she fully understands that the consequences will be lifelong sterility. A short time ago a medical man told me that some years after sterilising, at her own request, a female patient, she had bitterly complained that she had not understood that the effect would be lasting, and that she would *never* have any children. This would have been prevented by the course I have indicated. The next point is, the operation should never be performed upon minors, even at their own request or upon that of their parents or guardians. A few months ago this matter was raised in the columns of the medical journals. The questions asked were specific ones, and were: "Has a father the right to have his son (an epileptic, 12 years of age) sterilised, and is a surgeon legally and morally justified in carrying it out?" (*Lancet*, July 20th, 1911, p. 328.) Whether the object was to arouse a general discussion I do not know; certainly it did raise a good deal of discussion, but without, as is not unusual in such cases, the concrete question receiving any adequate answer. In my opinion, the answer to both queries is in the negative. A minor cannot make a legal contract; his parents or guardians are not entitled to make a contract for him which will bind him after he has reached full age, certainly not one which will be attended with lifelong consequences. Such might be done by the State in the general interests of the community, but the parent has no right to arrogate to himself the functions of the State. I hold, therefore, that operation in such a case would be quite illegal. With regard to the circumstances in which it is justifiable, I do not think I can do better than mention a case which occurred to me only a few weeks ago. I was consulted by two young persons as to the desirability of their marrying. They had become engaged some time previously without any such question entering their heads; but a course of eugenic literature had raised doubts, and they came to ask for advice. They were both well-educated people, independent, and moving in good society. The girl was somewhat neurotic and hyper-conscientious, albeit well developed and organically sound; but her family history showed a marked tendency to consumption. Two of her brothers, her father, and her father's brother and sister had died of phthisis. On the young man's side there was a strong history of insanity. One of his brothers was feeble-minded, another was epileptic, his father had had two, if not more, severe nervous breakdowns, two of his father's brothers and his father's mother had been insane in asylums, whilst the condition of other members of the family was not quite satisfactory. The patient himself was well developed and healthy, decidedly above the average in intellectual

capacity, had an excellent school and college record, but was somewhat unstable and inclined to be excitable. My experience of unions of this kind is that the offspring is very rarely healthy. Insanity or epilepsy is extremely probable, and if pregnancy, childbirth, or the early years of child-life should be accompanied by anything adverse, there is a strong probability that the offspring will be idiotic or imbecile. I, therefore, strongly advised against marriage. The pair were obviously deeply attached to one another and greatly disappointed, but I do not think they were unprepared for the opinion, for their next question showed that they had gone into the matter pretty thoroughly. They asked, would there be any bar to marriage provided no children were born, could the ordinary artificial methods be relied upon to prevent this, or did I think that sterilisation should be performed? Had the propagation of only one of them been contra-indicated, I should have tried to persuade them against marriage at all, on the ground of wastage of good material; but since this was so with both of them, and since there was evidently a real affection between them, I unhesitatingly advised in favour of sterilisation, and in so doing I consider that I was acting in the best interests of the pair as well as of the State. I think this case is a very good illustration of the circumstances under which we are justified in advising sterilisation—namely, where there is nothing in the condition of the individuals to contra-indicate marriage, but where the family history is such that propagation should not be allowed.

OTHER ASPECTS.

I have mentioned the subject of segregation. At the present time, although this is a recognised legal procedure with regard to several classes—*e.g.*, criminals, lunatics, idiots, imbeciles and inebriates, it is not adopted from eugenic considerations. But indications are not wanting that a very considerable advance has taken place in public opinion regarding this matter. I think there is very little doubt that the near future will see the recognition of the principle of segregation from the eugenic aspect. This will inevitably bring eugenics into still closer touch with medical science.

In conclusion, there is one other matter to which I may refer. The object of eugenics is not merely the eradication of existing degeneracy, but its prevention in the future. The prime and initial cause of this degeneracy is by no means fully understood, and it seems to me that this is a field in which even busy medical practitioners may find the opportunity of rendering incalculable service to the good of the race. I do not suggest that he can undertake laboratory work or extensive biometrical investigations, but he can carefully note and place on record many facts regarding the transmission of disease and the effects of adverse conditions upon offspring, and so considerably advance our knowledge of these important questions. The science of medicine, I may remind you, owes no little of its present position to the clinical work of capable and enthusiastic general practitioners. My opinion is that the initiation of that pathological condition of the germ plasm which culminates in degeneracy is to be found in the presence of disease and adverse environment, and any measures which will secure hygienic improvement and more efficient treatment will not fail to *prevent* unfitness in the future. Much progress has already been made on these lines, but there is still great need for improved facilities for the treatment of certain diseases, particularly, for instance, syphilis and gonorrhœa. It is to be hoped that the movement which is now on foot to secure greater facilities for the more thorough treatment of these conditions will have a successful issue. In so far as it aims at improving the general health of the community, the Insurance Act is a decidedly eugenic measure, and in this respect, I am sure, has the support of the medical profession; but nothing can be more disastrous to the working classes and to the State than inadequate medical attention, and it is because we feel that, as it stands, it does not admit of adequate treatment being afforded that we rightly object to

this measure. The health of the nation is, or should be, the concern of the State. It is unjust to impose the burden of its cost upon an already hard-worked and ill-paid profession.

It will be obvious that the time at my disposal has only admitted of a very brief review of the main points of contact between eugenics and medicine; each aspect I have dealt with might in itself form the subject of a separate lecture, but I trust I have said enough to show that the relationship is a very intimate one and one which has not been undeserving of our attention.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

GASTROSTOMY.—MR. WILLMOTT EVANS operated on a man, æt. 43, who had been admitted suffering from dysphagia. For the last three months the patient had experienced increasing difficulty in swallowing. At first he had only noticed that he had to chew his food more thoroughly than previously, but this was followed by increasing difficulty in swallowing, so that at the time of admission he was unable to take any solid food. Liquids were still able to pass the obstruction. He had lost a great deal of weight, probably 20 or 30 pounds, but his general health was still fair. He said he felt the food stop at a point opposite the upper border of the sternum, but an œsophageal bougie was able to pass easily until it reached an obstruction about twelve inches from the teeth, where it was arrested. A diagnosis was made of malignant stricture of the œsophagus, and it was decided to perform a gastrostomy.

An incision two and a half inches in length was made immediately to the outer border of the left rectus and about midway between the umbilicus and the xipho-sternal articulation. When the peritoneum was opened the stomach was easily found and was brought to the surface. A point was selected about midway between the two curvatures and rather nearer the cardia than the pylorus, and an incision made in the stomach wall sufficiently large to admit a No. 8 Jacques catheter. This was passed into the stomach for about a little more than an inch and fixed in apposition to the margin of the opening by means of catgut sutures. The stomach wall was then pushed inwards for about half an inch, and a purse-string suture passed through the walls of the stomach, but omitting the mucous membrane. It was drawn tight round the catheter. Two similar purse-string sutures were passed at half-inch intervals outside the first, so that a funnel-shaped portion of the stomach wall was made to project into the viscus, and at the apex of the funnel was the catheter. Two fixation sutures were inserted, one above and one below the opening into the stomach; each passed through the abdominal wall of one side of the incision, then through the greater part of the stomach wall, and lastly through the abdominal wall on the other side of the incision. When these sutures were tied the stomach was held up firmly against the abdominal wall. The incision was then sutured, a clip was placed on the catheter to prevent any egress of the gastric fluid, a gauze dressing was applied, and the patient returned to bed.

Mr. Evans said that there is still a good deal of difference of opinion as to the best time of performing the operation of gastrostomy in a case of obstruction of the œsophagus. When the operation was first introduced the danger attendant on it induced surgeons, and especially physicians, to postpone it to a very late stage of the disease, so that it was often performed on patients who were almost moribund. This practice, he thought, did not tend to improve the mortality, and the operation was greatly discredited. Though no one would nowadays advise postponement of the operation to so late a stage of the disease, yet many consider that the operation does not need to be performed until the patient has become incapable of taking any form of nourishment by the mouth. This

appeared to him to be unwise, for it must militate against the success of the operation if the patient is allowed to become weakened by a great diminution of the quantity of food taken. It seemed to him to be far wiser to operate as soon as the patient has definitely lost weight, for that, he considered, was an indication that he is no longer able to take sufficient food by the mouth. The choice of operation, he remarked, is simple; in his opinion no other form of operation is so good as that with which the name of Senn is associated, though it was not really invented by him. There are two great advantages in this operation: the first is that, when it is correctly performed, there is no risk of the escape of gastric contents, and the painful and troublesome excoriation of the skin, which at one time frequently occurred, cannot take place. There was, he said, a further advantage in this operation: if it is wished, it is possible to feed the patient on the operating table, and when the patient is in a very low condition for the want of food this is a point of no little importance. The catheter, he remarked, is stitched to the stomach wall by means of catgut sutures, so that it may become loosened spontaneously in a few days' time. For the other sutures silk is most suitable.

The patient recovered rapidly from the anæsthetic. There was no vomiting, and the first meal was administered about twelve hours after the operation; it consisted of half-a-pint of milk with a beaten-up egg and two drachms of malt extract. Similar meals were given every four hours during the day, but before long the quantity was increased to a pint at each meal. Within a week his weight began to increase, and when he left the hospital three weeks after the operation he weighed seven pounds more than when he was admitted. To overcome the dryness of the mouth which is usually present in cases of gastrostomy, he was allowed a cup of tea at each meal; the greater part of this he swallowed, but some of it he spat out after rinsing out his mouth with it.

SPECIAL REPORTS.

THE EIGHTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT LIVERPOOL, 1912.

[THIRD ARTICLE.]

[BY OUR SPECIAL REPRESENTATIVE.]

THE WORK OF THE SECTIONS.

THE work of the annual meeting was conducted in twenty sections, all of which were conveniently housed in the various buildings and class-rooms of the University of Liverpool. A brief summary of the more important proceedings appears below.

SECTION OF ANÆSTHETICS.

After the opening remarks of the President, Dr. Dudley W. Buxton, a discussion was opened by Dr. Felix Rood on intravenous infusion anæsthesia, describing his apparatus and *technique*. Mr. Alexander Wilson (Manchester) opened a discussion on the importance of affording the anæsthetist an opportunity of making a thorough examination of the patient some days previously to a contemplated operation. He contended that many difficulties would be avoided by a more intimate acquaintance between anæsthetist and patient. The intra-tracheal administration of ether was demonstrated by Dr. Ehrenfried (Boston, U.S.A.). The last morning was mainly occupied by a discussion on the use of alkaloidal bodies prior to inhalation, infusion or sub-dural injection, with a view to abrogating deleterious after-effects.

SECTION OF ANATOMY.

A discussion was opened by Sir William Macewen on the development and growth of bone, normal and abnormal. Among the interesting papers read on the second day may be mentioned those by Prof. Peter

Thompson (Birmingham) on the development of the diaphragm during the first month; by the President (Prof. William Wright) and Mr. R. G. Brown (London) on vestigial structures in relation to the epididymus; by Prof. Geddes (Dublin) on (a) an abnormal urinary system, (b) a case of pseudo-hermaphroditism, (c) an egg inside an egg. On the last day a combined discussion was arranged with the electro-therapeutical section on the normal stomach, which was opened by Dr. A. F. Hertz (London).

SECTION OF BACTERIOLOGY.

A joint discussion was held with the Section of State Medicine on *B. Coli*, its varieties and the significance of their occurrence in water supplies, which was introduced by Dr. A. C. Houston (Metropolitan Water Board, London), Dr. Chalmers (Glasgow) occupying the chair. A resolution was passed to the effect that no opinion should be passed as to the quality of a water for drinking purposes on bacteriological evidence alone apart from a local and topographical inspection of the sources of supply by a competent observer. The second day was occupied with papers, among which may be mentioned that by Prof. J. M. Beattie and Dr. A. G. Yates on variations in the morphological characters of bacteria and their reactions with sugars under different conditions, and that by Prof. E. Emrys Roberts and Dr. S. B. Walsh on the Brownian movement, with special reference to the anthrax spore. A discussion took place on the last day on the standardisation and control of vaccines, which was introduced by Drs. J. Eyre and J. Freeman.

SECTION OF DERMATOLOGY.

After a short address from the President, Prof. Walter G. Smith (Dublin), Dr. Arthur Whitfield (London) introduced a discussion on the nature, causation and treatment of seborrhœa and acne, the word seborrhœa being defined as "a secretion which leads to pathological complications." He was followed by Dr. P. S. Abraham (London), who laid stress on dietetic considerations and local treatment in acne. A valuable contribution towards the discussion by Dr. Sabouraud (Paris) was translated and read by Dr. R. McKenna. On the following day Dr. Lucien de Beurmann (Paris) read an interesting and highly technical paper on sporotrichosis, embodying the results of his own researches into the ætiology and pathology of this disease. Dr. J. L. Bunch (London) followed with a paper on the treatment of nævi, based on 2,000 cases, and by Dr. J. Goodwin Tomkinson (Glasgow) on the use of the vacuum electrode in in névrodermite. Mr. J. R. McDonagh (London) read a paper on a rational method of treating syphilis. On the Friday, Prof. Madden (Cairo) started the proceedings with a paper on a case of papilliform lesions (? lymphangiomata) of the scrotum. Dr. David Walsh (London) followed with a paper on traumatic dermatitis and other cutaneous lesions in relation to cardiovascular conditions, illustrated by coloured drawings. He showed that many chronic and recurrent skin affections owed their existence to the presence, often totally unsuspected, of some cardiac lesion. Dr. Norman Meachen (London) followed with a paper on morbid conditions of the nails: a plea for their more systematic study. Dr. L. Savatard (Manchester) contributed two short papers on sebaceous carcinoma and sarcoma on lupus scar tissue. A note on a case of xanthoma was read by Dr. Oram (Liverpool). A number of interesting skin cases were shown each morning before the meetings.

SECTION OF DISEASES OF CHILDREN, INCLUDING ORTHOPÆDICS.

The President, Mr. Robert Jones (Liverpool), called upon Mr. H. J. Stiles (Edinburgh) to open a discussion on the after-results of the major operations for tuberculous disease of joints. The importance of early diagnosis was insisted upon and the advisability of more extensive operative procedures was urged. He was followed by Messrs. A. H. Tubby, R. C. Elmslie, Douglas Drew, and others. A medical discussion took place on the following day on the dyspepsias of

children after the age of infancy which was opened by Dr. Robert Hutchison, followed by Drs. E. Cautley, H. R. Hutton, D. Fordyce, Paget Lapage, F. Eve and others. A valuable series of papers occupied the time on the last day, among which may be mentioned that by Mr. W. S. Haughton (Dublin) on a recent case of Lorenz operation, demonstrating by X-rays the development of the acetabulum; one by Dr. Murk Jansen (Leiden) on physiological scoliosis, and that by Mr. Kellett-Smith on some principles of the treatment of lateral curvature of the spine by exercise.

SECTION OF ELECTRO-THERAPEUTICS.

The proceedings were opened with an interesting paper by Professor Rutherford (Manchester) on the chemical action of the radiation of radium. He was of the opinion that actual radium or thorium salts should never be introduced unprotected into the system, but injections of water charged with radium emanations might be of great therapeutic value in a variety of morbid conditions. The rest of the morning was taken up with other papers on radium, Dr. E. Bellingham Smith (London) dwelling upon its physiological action on normal tissues and on cancer, a similar contribution being made by Mr. Ernest H. Shaw (London). Dr. W. Armstrong (Buxton) put in a plea for the radio-oxygen bath. Dr. Haenisch (Hamburg) read the first paper the next day on the X-ray treatment of uterine fibroids. A discussion then followed on ionic medication, opened by Dr. Lewis Jones. A contribution on the electrical treatment of the prostate gland was read by Dr. Snow (New York). On the last day a combined discussion took place with the anatomical section on the normal stomach, as mentioned above. This was followed by papers by Dr. A. C. Jordan (London) on peribronchial phthisis, by Dr. Hugh Walsham (London) on aortic aneurysm, and by Dr. E. Reginald Morton (London) on the X-ray diagnosis of some forms of arthritis, among others.

SECTION OF GYNÆCOLOGY AND OBSTETRICS.

After a brief address by the President, Professor Henry Briggs (Liverpool), a discussion was opened on the results of treatment of the inflammatory diseases of the uterine appendages, Dr. W. S. A. Griffith dealing with the medical aspect, and Mr. Christopher Martin from the surgical standpoint, being followed by Drs. Munro Kerr, Nigel Stark, F. W. N. Haultain, Amand Routh, Mrs. Scharlieb, Sir John Byers, and others. A joint discussion took place next day with the Section of Pathology on Eclampsia in which the principal speakers were Dr. J. W. Ballantyne (Ætiology), Dr. J. H. Teacher (Morbid Anatomy) and Sir William Smyly (Therapeutic Applications of recent research on the subject), being continued by Dr. Haultain and Dr. Oliphant Nicholson. On the Friday papers were read by Dr. R. W. Johnstone (Edinburgh) on chorio-angioma of the placenta, by Sir John Byers (Belfast) on rashes occurring during the puerperium, among others.

SECTION OF MEDICAL SOCIOLOGY

As might be expected, this section attracted large numbers, in view of the fact that subjects of vital interest to the profession as a whole were discussed therein. The President, Dr. J. C. McVail (Glasgow), having given a brief address, Dr. R. R. Rentoul (Liverpool) opened the first discussion on a public medical service under professional control, an abstract of which we hope to publish in our columns. Personally, he felt that better national results would be obtained if the Government made the employment of all doctors a branch of the Civil Service. He outlined a scheme for a public medical service, which he estimated would give each of the 20,000 doctors about £522 yearly, in addition to their public and other appointments, and if they could put a stop to the gross abuse of the voluntary hospitals this would add at least another £100 a year to the doctor's income. Unless they had the active co-operation of the staffs of the voluntary hospitals a public medical service would be a ghastly fiasco.

Dr. M. Dewar (Edinburgh) opened a discussion, limited to one hour, on the reform of hospital outpatient department, in the course of which he stated

that the hospital motto, "Open to all," was a great injustice to the general practitioners of the whole country, as it had developed a system of competition between those institutions and medical men, and had gone a long way towards sapping the independence of the public.

On the next day, Dr. J. C. McVail (Glasgow) opened a discussion on administrative measures consequent upon the compulsory notification of phthisis, and after this another short discussion was arranged for, the opener being Dr. A. G. Gullan (Liverpool), who introduced the question of administrative provisions for the prevention of malingering. He was followed by Drs. M. Dewar and Edgar Browne, among others.

A discussion on payment of medical services by capitation *versus* payment per attendance under the National Insurance Act was opened by Dr. H. Harvey, who put in a strong plea for the former method. Other speakers included Drs. R. P. Cooper, A. Stewart, C. G. S. Fleming, J. E. O'Sullivan and H. D. Ledward.

SECTION OF MEDICINE.

Dr. David Lees (London) opened a discussion on the diagnosis and treatment of early cardiac complications of rheumatism, being followed by Drs. Abrams (San Francisco), F. J. Poynton (London), Carey Coombs (Bristol), F. Langmead (London), J. Halls-Dally (London), and others.

On the next day a discussion took place on the pathogenesis, diagnosis and medical treatment of gastric ulcer, which was opened by Sir Bertrand Dawson (London), and continued by Professor R. Saundby, Professor Michell Clarke, Drs. Hertz, Bolton, Luff, Chalmers Watson, Tyson, F. J. Smith, and others. On the Friday a large number of interesting papers were read, including one by Majors Gibbard and Harrison, R.A.M.C., on the treatment of syphilis with salvarsan and neo-salvarsan; the quantitative regulation of the diet in diabetes, by Dr. P. J. Cammidge; demonstration of a more systematic posterior apical percussion and of the normal inter-spinous dulness as an aid to diagnosis, by Dr. William Ewart.

SECTION OF NAVY, ARMY AND AMBULANCE.

After Colonel Damer Harrison, K.H.S., A.M.S. (T.F.), the President, had opened the meeting, Capt. N. Dunbar Walker read a paper on factors affecting the marching powers of troops. He laid stress upon the fact that the load carried should not exceed one-third of the body weight. Subsequent speakers were Major-General Walter Lindsay, C.B., D.S.O., Surgeon-General W. Babbie, V.C., Deputy D.-G., A.M.S., Mr. T. S. Ellis (Gloucester), and others. A paper was then read by Fleet-Surgeon A. G. Wildey, R.N., on the more general use of iodine in first aid treatment. On the Thursday, Fleet-Surgeon A. W. Whitelegge, R.N., opened a discussion on eye-strain and its relation to gunnery, and Lt.-Col. Nathan Raw, R.A.M.C. (T.F.) read a communication on the treatment of syphilis with special reference to salvarsan.

SECTION OF NEUROLOGY AND PSYCHOLOGICAL MEDICINE.

Dr. Percy Smith (London) opened a discussion on the neuroses and psychoses of the climacteric, their prognosis and treatment, being followed by Dr. C. J. Macalister (General Medicine), Dr. T. B. Grimsdale (Gynaecology), the President, Dr. L. R. Oswald (Glasgow), Dr. Nathan Raw, and others. On the next day a discussion on compression paraplegia was opened by Dr. Ernest Reynolds and Sir Victor Horsley, followed by Drs. Risien Russell, Hinds Howell, Grainger Stewart, and Messrs. Donald Armour and K. W. Monsarrat, among others. Many interesting papers were read on the Friday, among which may be mentioned that by Dr. W. Maule Smith on the use of extract of brain tissue in the treatment of various forms of insanity; the results of the Wassermann reaction in 150 cases of mental disease, by Dr. David Nabarro, and the nature and treatment of epilepsy, by Dr. W. Alexander.

SECTION OF OPHTHALMOLOGY.

Mr. George Coats (London) opened a discussion on irido-cyclitis, with special reference to its pathology,

being followed by Mr. A. W. Ormond (London), Prof. Snellen (Utrecht), Mr. C. Worth (London), Mr. Harrison Butler (Coventry), Mr. Bishop Harman (London), and others. Dr. Karl Grossmann read a paper on the new Board of Trade standard of eyesight for ships' masters and officers. Most of those who took part in the subsequent discussion agreed with the reader of the paper that the new standard for form vision was too low, and the proposed new colour tests were condemned. Dr. G. Mackay (Edinburgh) opened a discussion on the second day on tuberculin and the treatment of eye affections, followed by Dr. Peel Ritchie and Dr. Marple (New York), among others. Mr. Sidney Stephenson (London) opened a discussion on the last day on salvarsan in relation to eye affections, in which Dr. J. Igersheimer (Halle), Dr. Maitland Ramsay, Mr. S. H. Browning, and others took part. Papers were read by Dr. Inglis Pollock and Dr. Bradburn.

SECTION OF LARYNGOLOGY AND RHINOLOGY.

The President, Mr. Middlemass Hunt (Liverpool) sketched the progress of this speciality in Liverpool, after which Professor O. Kahler (Freiburg) read a paper on excision of the œsophagus. A lantern demonstration was next given by Dr. Brown Kelly showing the passage of bismuth down the œsophagus, with special reference to the question of cardiospasm. The subject was further discussed by Drs. S. W. Hill, Walker Downie, Adolph Bronner, and others. A joint discussion was held on the Thursday with the Section of Otology on the education of the specialist in laryngology and otology, opened by Professor H. Mygind (Copenhagen), and continued by Professor H. S. Birkett (Montreal), Dr. Watson Williams, and others. On the last day a discussion on the treatment of chronic suppurative disease of the ethmoidal sinuses was opened by Professor M. Hajek (Vienna), and was continued by Dr. W. L. Ballinger (Chicago), Dr. Lambert Lack (London), and others.

SECTION OF OTOLOGY.

After some introductory remarks from the President, Mr. Hugh E. Jones (Liverpool), Mr. R. H. Woods (Dublin) opened a discussion on acute middle-ear suppuration, its neglect and proper treatment. He expressed a regret that the management of middle-ear conditions occurring in the course of the acute specific fevers was only imperfectly appreciated by the general physician. He was followed by Dr. Claude Rundle (Liverpool), Mr. W. M. Mollison (London), Professor Mygind (Copenhagen), Professor Ballenger (New York), and others. Dr. W. Milligan next read a paper on the value of decompressive operations in intracranial operations of otitic origin, with special reference to the treatment of otitic meningitis. A joint discussion took place the next day with the Section of Laryngology on the education of the specialist in laryngology and otology, opened by Dr. P. Watson-Williams. Dr. Kerr Love (Glasgow) read a paper on the prevention of deafness in non-suppurative cases, and Mr. G. J. Jenkins read one on the indications for Schwartz's operation.

SECTION OF PATHOLOGY.

Professor Lorrain Smith, F.R.S. (Manchester) started the proceedings by opening a discussion on the morbid anatomy and aetiology of Bright's disease. In the unavoidable absence of Sir Clifford Allbutt, his paper on the cardio-vascular changes was read by the President, Professor Walker Hall (Bristol). Dr. W. H. Gaskell (London) showed several renal sections taken by the freezing method. He was followed by Dr. F. Craven Moore (Manchester), and Dr. T. Shennan (Edinburgh), among others. A joint discussion was held on the Thursday with the Section of Gynaecology and Obstetrics on eclampsia, as mentioned above. The last day was occupied with the reading of many valuable papers, among which that by Dr. T. J. Horder (London) on the investigation of puncture fluids as an aid to diagnosis and treatment, Professor E. E. Glynn (Liverpool) on blood cultures in disease; and one by Dr. C. Bolton (London) on the causation of gastric ulcer, may be mentioned.

SECTION OF PHARMACOLOGY AND THERAPEUTICS.

Professor W. E. Dixon, F.R.S. (Cambridge) presided over this section and he announced the fact that for the first time a journal devoted entirely to pharmacology and experimental therapeutics would be published in this country, arrangements having been made with the "Journal of Pharmacology and Experimental Therapeutics," now published in America, to be issued simultaneously in New York and Cambridge under the joint editorship of Prof. Abel (Baltimore) and Prof. Cushny (London). Dr. A. Goulston (Exeter) then read a paper on dextrose in the treatment of certain forms of heart disease, Dr. O. T. Williams (Liverpool) following with one on cod-liver oil and its action in phthisis. Prof. Charteris (Glasgow) then read a paper on a comparison of the value of arsenious acid and of salvarsan in blood and other non-syphilitic diseases, and Prof. Marshall (Dundee) followed with one on clinical experiences with tetrahydropapaveroline hydrochloride. A discussion on the treatment of heart muscle affections, apart from valvular disease, was opened on the Thursday by Prof. G. A. Gibson (Edinburgh) and Prof. Cushny, while the proceedings concluded with a discussion on the rôle of calcium salts as therapeutic agents, opened by Prof. B. Moore and Sir James Barr.

SECTION OF PHYSIOLOGY.

The President, Prof. J. S. Macdonald (Sheffield) showed some interesting lantern slides on the various constituents of the blood, after which Dr. F. W. Mott, F.R.S. (London) opened a discussion on the biophysics and bio-chemistry of the neurone, followed by Prof. C. S. Sherrington, Dr. Wakelin Barratt, and Prof. A. B. Macallum. The next day a discussion was opened by Prof. B. Moore on the importance of substances present in minute amount in food, while a second discussion on tissue respiration was opened by Dr. H. E. Roaf (London). Dr. W. M. Vernon (Oxford) followed, dealing mainly with the process of oxidation and enzymes. The last day was occupied by the reading of papers, including those by Prof. C. S. Sherrington on some causes of uncertainty in reflex actions; observations on the production of apnoea, by Dr. T. H. Milroy; and remarks on the mechanics of progression, by Dr. T. Graham Brown.

SECTION OF STATE MEDICINE AND INDUSTRIAL DISEASES.

After the President, Dr. A. K. Chalmers (Glasgow) had delivered his opening remarks, a joint debate took place with the Section of Bacteriology on the rôle of the *B. coli* in water supplies, as mentioned above. A discussion on tuberculosis, together with the Section of Medical Sociology, was opened by Dr. J. C. McVail (Glasgow), followed by Dr. Marcus Paterson, Dr. Wynne (Wigan), Dr. Crofton (Dublin), and others. Dr. Erskine Young (Liverpool) read a paper on the Friday on the treatment of dental diseases in school children, being followed by Dr. Sim Wallace (London) on the same topic. Dr. C. H. Philips opened a discussion on the value of isolation in scarlet fever, maintaining that until we ceased to mass patients in large wards, so long would the hospitals be a failure. A highly technical paper was read by Dr. J. S. Mackintosh on the effect of intramigration on national health.

SECTION OF SURGERY.

The President, Prof. Rushton Parker (Liverpool) delivered a few introductory remarks, after which Mr. Harrison Cripps (London) opened a discussion on the treatment of carcinoma of the rectum, being followed by Messrs. C. A. Morton, G. Heaton, Sampson Handley, C. P. Childe, Leedham-Greene, Jordan Lloyd, Albert Lucas, and others. Mr. Hurry Fenwick (London) opened a discussion on the diagnosis and treatment of tuberculous disease of the urinary tract, in which Messrs. D. Newman, W. Bruce Clarke, P. J. Freyer, A. Fullerton, Swinford Edwards, Hugh Lett, and others took part. On the Thursday Dr. F. W. Cellison (Preston) demonstrated the electric lighting of a portable operating table or any domestic table used for operating. Among the papers read on the concluding morning may be mentioned that by Mr. J. F. Dobson (Leeds) on the treatment of gastric ulcer

by excision and partial gastrectomy; the results of filagree implantation in hernia, by Mr. Lawrie H. McGavin; the surgery of the sacro-iliac joint, by Mr. W. J. de Courcey Wheeler, and one thousand cases of total enucleation of the enlarged prostate, by Mr. P. J. Freyer.

SECTION OF TROPICAL MEDICINE.

Papers were read on the first morning on the subject of trypanosomiasis by Drs. Stephens, Fantham, Kinghorn and Yorke, and Professors Kleine and Mesnil. Dr. Weinburg contributed a paper on verminous toxins, and Prof. Castellani one on copra itch. Papers on leprosy and Leishmaniasis occupied the second morning. On the last day the practice was adopted of inviting the attendance of representatives of several of the large business firms who have offices in Liverpool to a debate organised on the sanitation of agricultural estates in the tropics, opened by Dr. Malcolm Watson (Federated Malay States), who maintained that it should be the aim of medical officers to demonstrate to estate managers the fact that sanitation adapted to the needs of a tropical agricultural population pays handsomely. Dr. W. Carnegie Brown and Dr. Law (British Guiana) followed on the same subject, and Dr. Stephens, who, in the absence of Sir Ronald Ross, was in charge, conducted a party of visitors over the School Museum.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS
ABROAD.

GERMANY.

Berlin, Aug. 3rd, 1912.

At the Medizinische Gesellschaft, Herr Richard Mühsam showed some cases of

PUNCTURED WOUND OF THE BRAIN,

and related some particulars concerning them. The cases were of interest, he said, not only on account of their rarity, but also on account of the very grave symptoms accompanying them and their rapid subsidence after operation.

As regarded rarity he observed that in the 22 years since the Moabit hospital was opened, with a great number of gunshot wounds of the skull only three cases of punctured wound had been admitted. The first was a case under Geheimrat Sonnenburg, the second under the speaker's predecessor Prof. Hermes, the third was a case of his own, and all three recovered after operation. In the large majority of cases of stabbing wounds of the head the brain was not injured, as the blow had not been sufficiently powerful to drive the knife through the bony walls.

The first case was that of a man of 26. Whilst in a drunken condition he had got mixed up in a fight, had received a stab with a knife in the region of the right parietal bone besides other injuries. He was said to have vomited, and from the accident station was sent into the hospital. He was a large, powerful man, very drunk, temp. 36.5, pulse 96. There was a punctured wound about 1cm. in length over the temporal bone; free from reaction, bruises on various parts of the head. The region round the wound moderately swollen, no sign of paralysis. Aseptic dressing applied. The next day the patient complained of headache, the pulse slowed to 60, left facial, left arm and left leg slightly paretic. Temp. at most 37.5. Three days later the paresis was better so that the patient could raise his arm.

The next day the paresis had returned with headache again, the pulse was tense between 60 and 70.

The day following, however, the symptoms were all worse again. In the morning the patient had a convulsion which was followed by many others, so that within one hour he had 15. At first only the left side was implicated, but later on the right also participated.

The X-rays showed a shadow (hæmatoma) beneath the puncture and an operation was immediately performed. Chloroform-ether narcosis was employed.

A splinter of bone was sticking in the dura, the brain substance not being punctured. The bone had been smoothly pierced by the knife. The dura was opened, and it was then found that the knife had penetrated the precentral gyrus, a quantity of blood and coagulum was removed; at a depth of 6 to 7 cm. the finger came to a cavity filled with clot. This was removed. The dura was then closed with the exception of a small slit through which a thin wick was inserted.

The next day (March 9th) the patient was much improved. On the 11th the patient had 10 typical attacks during the night, the tampons were removed, some blood still flowed, superficial dressing, after this no more attacks. Improvement was gradual and steady, and the patient was discharged on April 4th.

Case 2.—Patient admitted into hospital in a drunken condition November 4, 1891. The puncture was towards the back of the left parietal bone, passing through a very greasy hat and the bone of the skull. The wound was 2 cm. wide. No symptoms of cerebral disturbance present. No loss of consciousness. The next morning the patient's mind was clear, there was no vomiting nor any sign of paralysis, except for a complaint that the right arm felt weak; gait unsteady. The wound dilated and had been tamponaded on the patient's admission. At the operation it was seen that the wound had penetrated the brain itself, an opening about 1½ cm. in length was in the dura mater, through which a greasy bluish-red coloured mass protruded. No bleeding was going on and only a small coagulum was removed. Disinfection of the parts was completed by the Paquelin cautery. Recovery was uninterrupted.

Case 3.—Patient, æt. 32, was admitted January 27th, 1905. In a fight his opponent struck him with all his force with a knife on the left side of the skull. An attempt to withdraw the knife was unsuccessful, so the man was at once taken to the hospital.

Condition: The pocket-knife was stuck fast up to the handle in the left temporal bone. Operation: Incision 12 cm. in length, periosteum raised. Now it was seen that the weapon had caused a fracture which did not end with the knife opening. The wound was enlarged with hammer and chisel, and the knife removed. It was then seen that the blade of the knife had penetrated 6 cm. Two pieces of the blade had broken off and were removed separately. The wound in the brain which pulsated rather strongly and bled rather freely was tamponed. An aseptic dressing was applied. With the exception that the temp. rose on one occasion to 40 and went back when a drain was inserted, everything went well, the patient being discharged on March 18. The further course was not quite so satisfactory, as there was a deep canal in the centre of the wound, from which came a discharge of pus. On stooping and on running the man complained of giddiness, with headache, and there was a distinct weakening of intellect.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

BELFAST HOSPITAL FOR SKIN DISEASES.—The annual meeting of this hospital was held last week, when the medical staff report was presented by Dr. R. J. Purdon. It stated that the various appliances in use for the treatment of skin affections, lupus, etc., had been brought thoroughly up to date, and were giving most beneficial results. Dr. S. W. Allworthy also spoke of the work of the hospital, and referred specially to the large amount of tubercular disease treated, and the possible effects of the Insurance Act on such work.

MASONIC MEMORIAL TO THE LATE DR. CROSSLE, NEWRY.—A handsome brass tablet to the memory of the late Dr. Crossle was dedicated in St. Mary's Church, Newry, last Sunday afternoon, by His Grace the Lord Primate. The tablet, which was designed by Mr. J. Vinycombe, bears the inscription: "Mark the perfect man and behold the upright, for the end of

that man is peace.' In affectionate memory of Francis Clements Crossle, M.B., of Newry, who died on the 15th day of October, 1910, in the 64th year of his age. With strict integrity and with love and zeal for the good and welfare of the craft, he was over thirteen years Provincial Grand Secretary and for nine years Deputy Grand Master of the Masonic Province of Down. This tablet is placed here by the brethren of the province to commemorate the fraternal love and esteem in which they held him when living and to mark their sorrow at his death." His Grace gave an impressive address, and paid an eloquent tribute to the character of the late Dr. Crossle.

TUBERCULOSIS AND PUBLIC HEALTH.—At the monthly meeting of the City Council held last week, Dr. Thompson, Chairman of the Public Health Committee, said that his committee had hoped to present to the Council a complete scheme for the prevention and treatment of tuberculosis. They had, however, to adjourn the matter for the present, as they had no power yet to spend a single penny for this work. Under the Tuberculosis Prevention Act of 1908 all expenses under the Act had to be defrayed out of the poor-rate, and at present the ratepayers are spending £18,000 a year in the treatment of tuberculosis—£15,000 at the Abbey Sanatorium, which is administered by the Poor-law Guardians, and £3,000 contributed by the Corporation to the Forster Green Hospital.

QUEEN'S UNIVERSITY ATHLETIC GROUND.—All old students and friends of Queen's will be glad to hear that after many years of difficulties and delays, the matter of an athletic ground has been settled, and that in a most satisfactory manner. The committee in charge has, with the permission of the Senate, purchased for the sum of £10,100, free of rent, the property known as Old Forge, about a mile and a half from the University and a few minutes from the Malone Road tram terminus. The property comprises 74 acres, including the old polo ground, and is eminently suitable for its purpose. The money is in hand with the exception of a few hundreds, which can easily be raised, and the students ought soon to be established in grounds which will have few rivals in the universities of Europe.

DEATH OF DR. JAMES M'ILROY, BALLYCASTLE.—Widespread regret is felt in County Antrim at the death of Dr. James M'Ilroy, J.P., at the age of 67 years. He was born near Bushmills, in the north of County Antrim, and educated at Glasgow University, where he took the degree of M.B. in 1867. His whole professional life was spent in his native district, first for 22 years as Dispensary Medical Officer of Lavan, near Ballymoney, and then for 23 years as Officer at Ballycastle. Some six years ago he received injuries to his spine in a driving accident, and from these he never recovered, the end being due to septic trouble in the bladder and kidneys. He leaves a widow and four daughters, two of whom, Dr. Louie M'Ilroy and Dr. Jeanie M'Ilroy, have attained distinction in their father's profession in London and Glasgow. Dr. M'Ilroy was a personal favourite with rich and poor alike, and will be greatly missed in the county.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ROYAL MEDICAL BENEVOLENT FUND.
To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—His Majesty the King has been graciously pleased to grant to the British Medical Benevolent Fund the title of Royal, so that it will henceforth be known as the Royal Medical Benevolent Fund.

I shall be much obliged if you will assist in making known this act of the King's grace towards this long established and well-deserving Charity.

I am, Sir, Yours truly,

SAMUEL WEST. Hon. Treasurer.

11, Chandos Street, London, W.

July 31st, 1912.

OBITUARY.

MR. A. T. NORTON, C.B.

It is with profound regret that we have to record the death of Mr. Arthur Trehern Norton, C.B., F.R.C.S., of Leyfields Wood, Ashampstead, Berkshire, one of the proprietors of the MEDICAL PRESS AND CIRCULAR, which took place on Sunday last in a nursing home at Reading, after an operation for appendicitis. The deceased, who was 71 years of age, was the second son of the late Dr. Robert Norton, and he married, in 1868, Lucy Maude, the eldest daughter of Mr. E. Meredith Crosse, of Newhouse Park, Herts. He was one of the founders of the London School of Medicine for Women, and a member of the War Office Committee for the development of the Volunteer Medical Service, with which he had a special acquaintance, having been Surgeon-Lieutenant-Colonel and Commandant of the London Volunteer Medical Staff Corps. He was made a Companion of the Bath in 1897 in recognition of his efforts in the formation of the corps. He also held the Jubilee Medal and the Volunteer Officers' Decoration. For his services in the Franco-German War he was awarded the French war medal in gold, having done excellent work with regard to the ambulance arrangements. He was an Honorary Associate of the Order of St. John of Jerusalem, and Consulting Surgeon to St. Mary's Hospital, as well as Lecturer on Clinical Surgery in the Medical School, and he acted as Examiner in Surgery for the Society of Apothecaries and Durham University. Among his published works may be mentioned "Osteology for Students" and "Affections of the Throat and Larynx," and he also dealt with the anatomy of the eye. He translated and edited "Bernard and Huette's Operative Surgery and Surgical Anatomy." He was a member of the Authors' Club.

DR. W. H. CARRUTHERS, OF RUNCORN.

THE death has taken place with tragic suddenness of Dr. William Hodson Carruthers, of Halton, Runcorn. He was in the habit of doing his rounds in his motor car, and on the 22nd ult., he instructed his chauffeur on the way home to stop at the shop of Mr. J. H. Weston, chemist, Victoria Road. On arrival there, the chauffeur opened the car door, and, as the doctor did not immediately step out, glanced at him, and observed that his head had fallen on to his chest. Assistance was at once summoned, and the doctor was carried into a room adjoining the shop, but death had probably taken place before he was lifted from the car.

Dr. Carruthers was well known all over the countryside, in which his life was spent, and had the entire confidence of the people of Runcorn and the country gentry of the surrounding country. He was a son of the late Dr. Hodgson Carruthers, of Runcorn, formerly of Carlisle, and had practised locally for forty-five years. At one time he was house surgeon at Manchester Royal Infirmary. He was an M.R.C.S.Eng. (1867), and M.D. Edinburgh (1870). A man of great kindness of heart, he was beloved deeply by all sections of the community. The cause of death is assumed to be heart failure.

DR. T. KIRKWOOD, OF NEWCASTLE.

WE regret to record the death of Dr. Thomas Kirkwood, which has taken place at his residence at Westmorland Road, Newcastle, aged 62. The deceased, who qualified as M.B., C.M. Glasg., was a native of Dalry in Ayrshire, where his father, Mr. Thomas Kirkwood, was a well-known merchant. His early education he received in the Free Church School at Dalry. For a while, too, he was a pupil teacher in the school of his boyhood, and after that he studied at the Glasgow Free Church Normal Seminary, under the late Dr. Thomas Morrison. At the age of 20 he went as certificated assistant in the Glasgow Highland Society's schools, and taught there for two years. It was then that he resolved to follow the medical profession, and he went to Glasgow University where he worked under

Dr. McCall Anderson, Sir George McLeod, and Sir George Buchanan. Having completed his medical training he acted as assistant in Fauld House, Lanarkshire, thereafter removing to Rutherglen, where he remained a few years, acquiring further experience. Twenty-seven years ago he came to Newcastle, succeeding the late Dr. Scott in Westmorland Road, where he had lived ever since, carrying on a good class family practice in the city. Of a retiring disposition, Dr. Kirkwood lived in his practice, devoting himself wholeheartedly to it. He was held in high esteem by his medical brethren, with whom he was closely associated through the Clinical Society and the local branch of the British Medical Association. A Presbyterian, he was a constant attendee at the Westmorland Road Church. Dr. Kirkwood leaves a son, and his wife predeceased her husband in October last.

REVIEWS OF BOOKS.

ANÆSTHETICS. (a)

THE second edition of this little text-book appeared some six years ago, when it formed No. VII. of the "Medical Monograph Series." The favourable opinion expressed of the book at that time has been fully justified by the call for a third edition. In this edition the author has been able to effect some improvements, the chief change being in the description of the open method of administering ether. English anæsthetists never seem to have been so much at home with the use of this drug as have their colleagues in other countries. With the older methods of administration of ether it was quite possible to obtain almost uniformly bad results unless the anæsthetist had the experience necessary to master the rather difficult *technique* of its administration. With the open method, however, if one obtains an anæsthesia at all, it is likely to be good, and consequently we have great hopes that the introduction of this method will lead to the more general use of the drug in England, a course of procedure which has for many years been advocated in the pages of this journal. We congratulate the author on the success of his book and on the good work which has earned that success.

SEA-SICKNESS. (b)

THIS volume should be widely read, for the feelings and interests to which it appeals are thoroughly cosmopolitan. But we confess to having felt somewhat discouraged by the perusal of the first sentence of the preface, in which the words of our author are thus written: "Seasickness is ordinarily looked upon as a trifling ailment." Surely anybody who has even but *seen* the symptoms of the original *NAUS-æa* must feel convinced that the condition is hardly one that can justly be classified under the head of "trifling." And our American cousins have not only felt, but written upon the subject, both appreciatively and philosophically. Does not sea-sickness recall the amateurish therapeutics of "the common or garden" methods of curing a cold, one of the prescriptions of which made America's least mortal humorist reject everything removable from his person by the bucco-oesophageal route, except his eternal soul? And has not the most entertaining and popularly impressive of America's amateur cynics reminded his readers that sea-sickness is one of the very best temporary cures for "pride and impudence," by reason of the undeniable fact that "a man who is going to vomit never puts on any airs"?

The present booklet, which would appear to represent an effort to popularise the author's much larger work on the same subject, noticed a few weeks ago in these columns, presents its materials not only carefully and skilfully prepared, but lucidly

(a) "Anæsthetics—A Practical Handbook." By J. Blumfeld, M.D. Cantab. Third Edition. 8vo. pp. vii. and 143. London: Baillière, Tindall and Cox. 1912. Price 3s. 6d.

(b) "Sea-Sickness and Health: A Manual for Travellers." B. Joseph Byrne, A.M., M.D., LL.B. Crown 8vo. Pp. 128. London: H. K. Lewis. 1912. Price 4s. net.

written and arranged. The author takes as little as possible for granted. And his view point is succinctly formulated on pp. 36-7: "Without going into tedious details, it may be stated at once that the writer's experiments have shown very conclusively that sea-sickness is caused by repeated, irregular stimulation of the vestibular nerve. . . . The special function of the vestibular nerve is the automatic (non-voluntary) control of movements involved in maintaining the equilibrium of the body." This appears to be a very reasonable view—in the light of our twentieth-century physiology. We are less disposed to take in prophylactic seriousness the following observations: "Sea-sickness is frequently aggravated and the attack prolonged by injudicious eating. At the commencement of the journey, and sometimes even during the progress of the illness, there is a tendency on the part of travellers to take too much food, or food that is improperly adapted to the needs of the occasion. In the height of their sea-sickness the author has seen individuals, mostly young women, eat oranges almost immediately after an attack of vomiting." We feel sure that the author is gifted with a Celtic imagination. He writes clearly and chooses his expressive words and phrases with judgment. His cognomen is distinctly suggestive of Hibernian lineage. And, if we are not always convinced by his opinions and the reasoning on which they have been based, we know of no physician who has published his views on this troublesome, and somewhat ungrateful, topic under whose professional protection we would so gladly cross the ever-narrowing "herring-pond" which unites the old country to the *Greater Ireland* of the Great Western Republic.

LETTERS OF WILLIAM HARVEY. (a)

WILLIAM HARVEY died on June 3rd, 1657, and year by year since that time the Harveian Lecturers have vied with each other in the relation and discovery of facts concerning the life and work of the great physiologist. In spite of all this labour and research, Dr. Mitchell has been able to publish for the first time some ten letters written by Harvey which are full of interest. The discovery of these letters is due to the work of the Royal Historical Manuscripts Commission, and it is to the courtesy of the Commissioners, through the good offices of Sir William Osler, that Dr. Mitchell has been able to issue them in their present form.

The letters date from 1636, when Harvey accompanied Lord Arundel on his embassy to the Palatinate. During this time Harvey obtained permission to visit Italy, but when he reached Treviso he was put in quarantine as one who was suspected of being infected with the plague. In these letters Harvey makes bitter complaints to Basil, Lord Feilding, Ambassador at Venice, of his treatment by the authorities at Treviso, of how he had to sleep on the grass, and was kept a prisoner though he had important business in Italy—treatment, too, under which he exhibited anything but the stoic temperament.

The bibliography compiled by Mr. Charles Perry Fisher, Librarian of the College of Physicians of Philadelphia, is a most valuable work, for which all medical historians are much in his debt.

SURGICAL TECHNIQUE. (b)

This book is divided into four parts, the first dealing with preliminary considerations, such as surgical bacteriology, infection, and disinfection. A special chapter has been added on the standardisation of disinfectants. Part II. deals with prophylactic disinfection. The author deals widely with the question whether gloves should be used or not when operating,

(a) "Some recently discovered Letters of William Harvey with other Miscellanea." By S. Weir Mitchell, M.D. With a Bibliography of Harvey's Works by Charles Perry Fisher. 4to. Pp. 55 and II plates. Philadelphia: 1912. Transactions of the College of Physicians of Philadelphia.

(b) "Modern Surgical Technique in its Relations to Operations and Wound Treatment." By C. Yelverton Pearson, M.D., M.Ch., F.R.C.S., Professor of Surgery, University College, Cork, &c. Second Edition, revised and enlarged, pp. 484. Illustrated with two coloured and other plates, and 129 illustrations in the text. London: John Bale, Sons and Danielsson, Ltd. 1911. Price 10s. 6d. net.

and quotes the views of many well-known surgeons; he sums up his opinion in a sentence: "It is not essential for every surgeon to wear gloves when operating in 'clean cases,' but each surgeon must satisfy himself by experiments that the method of hand disinfection which he adopts is capable of securing practical disinfection of his own hands." Parts III, and IV. consider wound and operative *technique* respectively. The illustrations are simple and clear, and a good index is provided. The book should prove useful to senior students and those about to embark on surgical practice.

THE KING'S EVIL. (a)

ENGLISH students of the history of medicine owe a debt of gratitude to the Fitzpatrick Lecturers for the works they have published since the establishment of these lectures. Not the least part of this debt is due to Dr. Crawford for the interesting book before us, which belongs to a good class of work and in that class takes a high place.

The story of the King's Evil and its cure by the Royal touch wanders through one of those many by-paths of medical history which are as full of interest as they are clouded by obscurity and error. For a long time it was believed in these countries that the power of curing the disease by touch was one of the prerogatives of our Royal house, transmitted by the saintly Edward the Confessor from king to king. In France, on the other hand, this faculty was looked on as the right of the Royal house of that country, a right which the English kings had merely borrowed from their Royal neighbours.

Dr. Crawford has been able to show that the custom is in all probability derived from the much older idea of the divine nature of healing in general, associated with the divine right of kings. Whatever may have been the origin of the practice, there is no doubt as to the extent of it in England and elsewhere. In England the practice continued down to the accession of the house of Hanover, when so much that was picturesque in the Royalty of England finally disappeared. Queen Anne was apparently the last English sovereign to exercise the Royal prerogative in this as in certain other particulars, and she is recorded to have "touched" Samuel Johnson, who "was then but thirty months old." Evidence has been adduced to show that the belief of the masses in the efficacy of the Royal touch was fostered and used for political purposes by those in high places, but that this belief was not confined to the masses is also evident from its adoption by such men as Robert Boyle and Swift, the latter of whom was an anxious suppliant for the Royal favour on a young protégé.

That cures followed this method of treatment is almost certainly true, and need excite no wonderment when we remember the results attributed to various quack remedies down even to our own times. Greatrakes, Mesmer, St. John Long, and a host of others could point to a lengthy list of successes in support of their claims to cure disease, and though these claims were contested by the faculty, and were in every case eventually shown to be largely exaggerated, still there remained a residuum of cures which could not be explained away. Although considerable progress has been made in psychology in recent times, this progress has not been anything like so rapid as has been the progress in our knowledge of the physical and natural sciences, and we are still far from being able to explain the interaction of mind and matter. Whether mental processes can directly influence physical processes is still in dispute, as indeed is the problem whether there is any absolute distinction between mental and physical processes.

While doubts exist on such fundamental points as these it is useless to hope to be able to explain how the mere mental influence, if one may use such a term, of one individual can modify the tissue changes of another. Experience seems to teach us that it can, but gives us no idea how it does so. In the presence

(a) "The King's Evil." By Raymond Crawford, M.D. 8vo., pp. 187, with nine plates. Oxford: The Clarendon Press. 1911.

of so much ignorance one must be careful how one contradicts experience on mere *a priori* considerations of impossibility. A study of the book before us shows that, like ourselves, our forefathers felt that after the elimination of all the frauds and coincidences there remained a number of phenomena not explained by existing knowledge.

COMMON DISEASES OF CHILDHOOD. (a)

It must be distinctly understood that this is in no sense a text-book of children's diseases. It is rather a collection of articles on some of the commoner conditions met with in early life; and herein lies its great value to the practitioner, for within its pages are discussed subjects which, for lack of space or some other consideration, are either scantily treated or passed over altogether in the recognised text-books. Each chapter in this book is really an essay or article on some particular disease or morbid condition. In this way the author considers no fewer than fifty-three of the maladies incident to childhood, as well as some other topics such as infant feeding. The author very rightly condemns the use of barley-water as a diluent, and points out that it may be a cause of rickets, and not uncommonly gives rise to gastrointestinal disturbances. He, therefore, favours plain water as the diluent in making up milk mixtures for infant-feeding. Raw milk must never be used, as the risks of tuberculous infection are always present. He says, in fact, that, as the result of his own observations, he finds that 29 per cent. of the cases of tuberculosis occurring in childhood are due to alimentary infection.

The subject of curd-indigestion is one of great importance, and this forms a special study in one of the chapters of this book. In the treatment of this condition Dr. Still recommends citration of the milk, or, failing that, peptonisation or feeding with whey. He does not condemn patent foods altogether. He thinks they sometimes have their place in infant feeding if intelligently employed. It is, perhaps, invidious to single out any particular chapter for special commendation where all are so excellent, but we must confess that the one dealing with tuberculosis is, in our opinion, the best in the whole book. It conveys to the mind of the reader a word-picture of tuberculosis as it is met with in childhood which is at once striking and unique.

The value of this book lies in the fact that it is an exposition of the writer's own experience, and the result of his own personal observations over a lengthy period. The book is, therefore, stamped with an originality rarely met with, which renders it of great service as a work of reference by students of pædiatrics.

In this edition several alterations have been made in order to bring the book into line with modern teaching; while minor additions have been made to the text which add considerably to its usefulness. The publication of a fresh edition within two years of the appearance of the first is in itself a proof of the service which the author has rendered to the profession in writing it.

AMERICAN MEDICAL BIOGRAPHY. (b)

SINCE William Munk published in 1861 his Roll of the Royal College of Physicians of London, which reached its second edition in 1878, no such book of medical biographies has, as far as we know, been issued in the English language. Dr. Kelly has been able to collect the biographies of some twelve hundred medical worthies of the United States and Canada, which, with many portraits, he has compressed into two handy octavo volumes.

(a) "Common Disorders and Diseases of Childhood." By George Frederick Still, M.A., M.D. Cantab., F.R.C.P. Lond., Professor of Diseases of Children, King's College, London; Physician to the Hospital for Sick Children, Great Ormond Street. Second Edition. London: Henry Frowde and Hodder and Stoughton. 1912.

(b) "A Cyclopedia of American Medical Biography, comprising the Lives of eminent deceased Physicians and Surgeons from 1610 to 1910." By Howard A. Kelly, M.D. Illustrated with Portraits. In two Volumes. 8vo., pp. lxxxv., 424, vii. and 515. Philadelphia: W. B. Saunders Company. 1912.

Only those who have tried to collect information about the lives of those who are long dead can appreciate the great labour involved in such a work, and as one of those we tender to the author our sincere thanks. The articles, though brief, are not scrappy, and the information, as far as we have been able to test it, is quite trustworthy. In the introduction Dr. Kelly gives a short historical sketch of the growth of American medicine, contributed by various authors and interspersed with valuable bibliographical references.

The book is printed in clear type, and the illustrations are admirably executed. We congratulate all concerned in the publication of the work, which should find a place on the shelves of every medical library.

LABORATORY REPORTS.

CLINICAL USE OF JUNORA.

REPORTS have now been received from a number of practitioners upon the clinical use of Junora wine, good results having been obtained from its employment as a medium for administering the organic glycerophosphates of lecithin, in the treatment of many forms of malnutrition and nervous debility. It is claimed that in practice, as well as under analysis Junora exhibits several marked differences from ordinary medicated wines. Among the points of difference emphasised are the following:—(1) The basis of Junora is a dry wine, it being entirely free from the sweetness which so often leads patients into unintentional intemperance. (2) The principal effects of ordinary medicated wines are due to a high alcohol percentage, whilst the meat, malt or other nutritive constituents in some of them are almost negligible. Junora is an alcoholic beverage because alcohol is the only practicable solvent for lecithin; but the alcohol percentage is as low as is consistent with the preservation of the lecithin-products in good condition. (3) The phosphoric acid present in organic combination, to which the nutritive value of Junora is mainly attributed, is approximately 0.0241 gramme per 100 c.c. This represents one grain of lecithin per fluid ounce, and is sufficient to explain the claim made on behalf of Junora, that it is primarily a nutrient, in contradistinction to ordinary medicated wines, which are primarily stimulant.

NEW PREPARATIONS.

BURROUGHS WELLCOME'S "VAPOROLE" PITUITARY EXTRACT 0.5 C.C.

FROM the clinical point of view, one of the most notable results of the investigations on the internal secretions of the ductless glands has been the preparation and introduction into therapeutics of an extract of the infundibular portion of the pituitary body. Such an extract, when injected intravenously or intramuscularly, raises the blood pressure and keeps it raised, acts as a stimulant of plain muscle, particularly of the uterus, slows and strengthens the heart-beat and causes profuse diuresis. All these actions have been taken advantage of clinically, and the extract has been successfully used in shock, in post-partum hæmorrhage, and after labour generally, in cases of intestinal paresis and atony following operations, in typhoid and other fevers, and as a diuretic. In a large number of the cases recorded in the literature, the preparation used has been "Vaporole" Pituitary (Infundibular) Extract, a sterilised preparation issued by Messrs. Burroughs Wellcome & Co. This has hitherto been available only in quantities of 1 c.c., but as a result of its more extended use, and to provide further convenience in dosage, it has now been issued also in containers of 0.5 c.c. "Vaporole" Pituitary (Infundibular) Extract, 0.5 c.c., is packed in boxes of six hermetically-sealed containers, and, being sterile, is ready for immediate injection.

MEDICAL NEWS IN BRIEF.

The Royal Sanitary Institute Congress at York.

H.R.H. PRINCE ARTHUR OF CONNAUGHT opened the Health Exhibition in the Exhibition Buildings, York, last week, in connection with the Congress of the Royal Sanitary Institute. His Royal Highness was received by the Lord Mayor of York (Alderman Norman Green), Chairman of the Local Committee of the Sanitary Congress, the Recorder of York (Mr. H. T. Kemp, K.C.), the Sheriff of York (Councillor J. B. Inglis), the Chairman of the Council of the Royal Sanitary Institute (Mr. H. Percy Boulnois), the Chairman of the Judges (Mr. W. C. Tyndale), the Town Clerk of York (Mr. Henry Craven), the Director and Secretary of the Royal Sanitary Institute (Mr. W. E. White-Wallis), the Local Secretaries of the Congress (Dr. E. M. Smith, M.D., D.P.H., Medical Officer of Health, and Mr. F. W. Spurr (City Engineer and Surveyor), and the Chairman of the Congress Committee (Mr. H. D. Searles Wood).

An address was presented to His Royal Highness by Mr. H. Percy Boulnois, Chairman of the Council of the Royal Sanitary Institute, to which Prince Arthur replied.

The work of the scientific sections began on the 30th ult., when the various Presidents gave their addresses, and many interesting and important discussions took place. In the afternoons visits and excursions to the various places of interest in the city and neighbourhood took place.

A Case of Plague in Liverpool.

It is reported that a boy, *æt.* 7, was admitted to the Royal Infirmary, Liverpool, on July 25th, and operated upon for supposed appendicitis. A gland was removed from the groin and was found to contain plague bacilli. This diagnosis has been confirmed at the laboratory of the Local Government Board. The source of infection cannot at present be stated definitely. All precautions are being taken to prevent the possibility of spread of the disease, and no further case has occurred. The patient came from the neighbourhood of the docks, where there was a likelihood of foreign rats having been brought in.

The Welsh National Memorial Association.

It is reported that peace has now been made between the British Medical Association and the Welsh National Memorial Association. The State Sickness Insurance Medical Committee of the British Medical Association have held an interview with Mr. David Davies, M.P., Mr. D. W. Evans (Hon. Secretary), Dr. Marcus Paterston (Medical Director), and Dr. W. E. Thomas (a member of the Executive Committee of the Welsh National Memorial Association), and in consequence all matters in regard to the Fund and doctors have been satisfactorily settled. It was stated that if the two doctors who had resigned re-applied they would be re-appointed under the Fund.

Torquay Carnival.

WITH the object of further popularising Torquay as a health and pleasure resort, the Corporation has arranged for a carnival to be held on August 17th. An installation of a variety of medicated baths is being established, and a new concert pavilion has been erected in the Princess Grounds at a cost of £40,000. This building will be opened on the day of the carnival with a concert given by an operatic party from the London Opera House, headed by Miss Felice Lyne.

Cure for Sleeping Sickness.

A RECENT telegram dated Berlin to a Liverpool journal announced that Professors Brieger and Krause believe they have discovered a permanent cure for sleeping sickness. The methods hitherto tried have proved effective only temporarily. Over a thousand experiments have been made on rats and guinea pigs with the new cure, and have proved its power. Practical tests are now to be made upon sufferers from the malady in German, British, and Belgian colonies in Africa.

London School of Tropical Medicine.

THE following have passed with distinction the examination of the 39th session, May-July, at the London School of Tropical Medicine:—Major W. P. Chamberlain (U.S. Army), M.D. (U.S.A.); Captain W. Lapsley (I.M.S.), M.B., R.U.I.; F. C. McCombie, M.D. (Lond.); Captain H. Emslie Smith (I.M.S.), M.B., Ch.B. (Aber.); Major H. R. Price (I.M.S.), M.B., F.R.C.S.E.; W. Allen (Colonial Service), M.B., Ch.B., D.P.H.; S. L. Brohier (Colonial Service), M.R.C.S., L.R.C.P., D.P.H.; W. J. Geale, L.R.C.P. and S.E.; J. E. L. Johnston (Colonial Service), M.B., B.S. (Lond.), M.R.C.S. L.R.C.P.; A. H. Owen (Colonial Service), M.R.C.S., L.R.C.P.; B. Spearman (Colonial Service), M.B., B.C. (Camb.).

Royal College of Physicians and Surgeons of Edinburgh and Royal Faculty of Physicians and Surgeons of Glasgow.

THE following candidates have passed in the examinations held in Glasgow in July, for the triple qualification of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow:—

Final Examination.—L.R.C.P.E., L.R.C.S.E., I.R.F.P., and S.G.:—James Grant Morrin, Glasgow; Frank Walter White, Gosforth; Hormazd Ardeshir Topalia, Bombay; George William Mason, Pontypool, Mon.; Thomas Nicholson Wilthew Hexham; John Peter Carroll, County Cork; Joseph Moses Coplans, London; Leopoldo Cajitano Mascarenhas, India; Kul Want, India; Edward Charles Hamilton, Edinburgh; Furdon Framii Keravalla, India; Patrick Walsh, Kilfinane, County Limerick.

Conjoint Examinations in Ireland.

THE following candidates have passed the summer examination of the Royal College of Physicians and the Royal College of Surgeons as undernoted:—

Preliminary Examination.—F. J. Bowers, T. J. Clune, J. Cusack, J. L. Farnon, J. Geraghty, F. G. Hall, V. Hawkins, P. Hegarty, J. F. Holmes, L. B. Leonard, M. O'Donnell, M. P. O'Meara, W. Robinson, A. Y. Sloane, R. J. Tate, H. C. Williamson.

First Professional Examination.—Miss E. Budd (with honours), Miss M. McMullin (with honours), B. Hirson (with honours), T. S. Ambrose, H. M. Alexander, H. E. Andrews, D. Boland, M. Bradley, J. F. Coffey, T. Curran, E. C. H. Ewart, D. H. Ferris, J. A. Fretton, F. B. Harrison, H. Levison, E. McCarthy, T. F. Moran, C. Murray, J. P. Pegun, C. W. Robinson, J. P. Sheridan, G. C. L. Woodroffe.

Second Professional Examination.—J. C. Cunningham, J. C. Fergusson, F. Fitzgibbon, C. E. H. Gater, J. W. E. Graham, J. Hegarty, O. J. M. Kerrigan, W. Lumley, W. G. D. McCall, W. G. McConnell, F. R. H. Mollan, J. O'Brien, Y. A. Power, P. O'C. Redmond, L. M. Rowlette, T. Ryan, R. A. Ryan, T. H. Sarsfield, M. A. Sullivan, J. A. Watson, Miss M. F. R. Welphly.

Third Professional Examination.—R. J. Brookes (with honours), J. Lanigan (with honours), R. A. Austin, H. A. S. Deane, G. S. Douglas, F. B. McTavish, J. J. O'Connell, H. O'Donoghue, J. J. Reynolds, M. Shipsey, F. M. Taylor.

Final Professional Examination.—W. I. Adams, P. J. Burke, U. L. Bourke, H. C. A. T. Cannon, W. H. Condell, M. Garry, J. Good, R. M. Gordon, R. F. J. Griffith, F. Hanigan, M. J. Hillery, J. M. Horan, W. H. Johnston, T. Kennedy, M. Meehan, F. P. McDermott, C. Molan, H. E. O'Brien, A. A. O'Connor, J. C. O'Farrell, A. J. Patterson, D. P. H. Pearson, J. B. Power, S. Punch, M. Quinlan, Miss B. Sieff, V. J. White, G. Young.

Examination for the Diploma in Public Health.—B. Flood, L.R.C.P. & S. Edin. (with honours); J. Ghosh, L.M. & S., Bombay; A. A. Gomes, L.M. & S., Ceylon; C. Greer, M.R.C.P.I., F.R.C.S.I. (with honours); M. E. Kayton, L.R.C.P. & S., Edin.; G. S. Levis, L.R.C.P. & S.I.; E. C. Mulligan, L.R.C.P. & S.I.; J. McKeague, L.R.C.P. & S., Edin.; N. R. Ussher, L.R.C.P. & S.I.; W. Venables Williams, L.R.C.P. & S., Edin.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature* or *Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

M.B.Glasg. (London, E.).—It has been clearly shown that uncultivated typhoid bacilli die more rapidly in raw water than their cultivated relations. Dr. Houston has also proved that "even a week's storage of raw water is an enormous protection, and less than a month's storage an apparently absolute protection against typhoid fever."

PUZZLED.—Proptosis of the left broad ligament has been recently assigned as a cause of constipation in women. Accompanying this are such signs as left iliac pain, increased by exertion, flatulent distension of the abdomen, occasional passage of mucus per rectum and gastric disturbances.

INTERNATIONAL CONGRESS OF OBSTETRICS AND GYNAECOLOGY IN BERLIN.

The proceedings of this Congress will commence on Monday, September 9th, when the International Organisation Committee meets. The discussions will commence on the Tuesday, and will continue until the following Thursday. Full information may be had from the Honorary Secretary to the Congress.—Dr. E. Martin, Berlin N., 24, Artilleriestr. 18.

POST-GRADUATE (Southend).—The Assistance Publique of Paris comprises thirty-one hospitals, aggregating 15,584 beds, which total is nearly doubled on adding the orphan asylums, etc., so that there is an abundance of clinical material available for clinical instruction.

G. P. (N. Devon).—Hypodermic injections of pituitrin have been used with great advantage in labour, the third stage of which is said to be materially facilitated without the occurrence of uterine relaxation. In 21 cases in which it was employed by Fries it invariably succeeded in increasing the strength and effectiveness of the pains.

MR. S. R. (Hereford).—The sale of sweets containing a syrupy liquid enclosed in chocolate, in which capsicum was found, was withdrawn after representations had been made to the manufacturers. It is most undesirable that any pungent drug of this nature should enter into the composition of sweets sold to children.

A YEAR'S WORK AT DAVOS.

At the ninth annual general meeting of the supporters of the Queen Alexandra Sanatorium at Davos, held the other day, it was stated that Lord Balfour of Burleigh, the President, was preparing an appeal for extra funds, as fewer patients were resident in summer than in winter. The enlargement of the sanatorium, in accordance with the wishes of the donor of £25,000, had been commenced. Dr. Barker, who had recently returned from a visit to Davos, had reported favourably upon the general condition of affairs in the sanatorium, but he regretted that too much economy had to be practised with regard to medical records of research work.

DA. H. L. McC. (Little Grosvenor Street, W.).—Your paper was unavoidably crowded out at press, but it is marked for speedy insertion. The alteration has been made as requested.

DR. V. PLETH (Mexico).—The new blood-counting pipette described by Mr. D. Thomson in THE MEDICAL PRESS AND CIRCULAR for April 24th, No. 3807, may be obtained from Messrs. Baker, 244, High Holborn, W.C. The price, we believe, is 10s. 6d.

Appointments.

ARMOUR, DONALD, F.R.C.S.Eng., Surgeon to the West London Hospital.

ATKINSON, J. A., M.B.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Newnham District of the county of Gloucester.

CLEMENTS, J. H., L.S.A.Lond., Medical Officer to the Winkleigh District by the Torrington Board of Guardians.

D'ESTERRE, J. NORCOTT, L.R.C.P.Lond., M.R.C.S., L.S.M.S.A. Lond., Registrar to the Kensington and Fulham General Dispensary, Earl's Court, S.W.

DOUGLAS, W. R., F.R.C.S.Eng., Assistant Surgical Officer to the Manchester Royal Infirmary.

EDWARDS, F. S., F.R.C.S.Eng., Consulting Surgeon to the West London Hospital.

GRAY, H. TERRELL, F.R.C.S.Eng., Assistant Surgeon to the West London Hospital.

HOWELL, C. M. HINDS, M.D.Oxon., F.R.C.P.Lond., Assistant Physician to Out-patients at the National Hospital, Queen Square, W.C.

JONES, F. WOOD, M.B.Lond., Lecturer and Head of the Department of Anatomy at the London School of Medicine for Women.

MACDONALD, S. G., F.R.C.S.Eng., Surgical Registrar to the West London Hospital.

WILLIAMS, IDWAL J., M.B., Ch.B.Liverp., Assistant Resident Medical Officer to the Mill Road Union Infirmary, Liverpool.

Vacancies.

Down District Lunatic Asylum.—Junior Male Assistant Medical Officer. Salary £130 per annum, rising by annual increments to a maximum of £150 per annum, with extras. Applications to the Resident Medical Superintendent, Downpatrick. (See advert.)

Nottingham General Dispensary (Branch).—Resident Surgeon. Salary £180 per annum; Assistant, salary £160 per annum, with apartments (not board), attendance, light and fuel. Applications to C. Chessman, Secretary, 12, Low Pavement, Nottingham.

Staffordshire County Asylum.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board and washing. Applications to the Medical Superintendent.

Nottingham General Hospital.—Senior House Surgeon. Salary £120 a year, with board, lodging and washing in the Hospital. Applications to the Secretary.

City of Birmingham.—Assistant Medical Officer of Health. Salary £250 per annum. Applications to the Medical Officer of Health, the Council House, Birmingham.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, washing and attendance. Applications to the Medical Superintendent.

Royal Victoria Infirmary, Newcastle-upon-Tyne.—Resident Medical Officer. Salary £200 per annum, with board and residence. Applications to the House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne.

District Infirmary and Children's Hospital, Ashton-under-Lyne.—Senior House Surgeon. Salary £120 per annum, and fees, board, apartments and washing provided. Applications to the Honorary Secretary, Leonard Bottomley, Esq., M.A., LL.D., 120, Stamford Street, Ashton-under-Lyne.

Births.

DICKINSON.—On July 29th, at Grey Friars, Hereford, the wife of Harold Bertie Dickinson, M.D., F.R.C.S., of a daughter.

MELLANBY.—On July 28th, at 25, Ellerker Gardens, Richmond, Surrey, the wife of John Mellanby, M.D., of a daughter.

SCORE.—On July 30th, 1912, at Byron's Lodge, Granchester, Cambridge, the wife of Dr. Lewis Shore, of a daughter.

Marriages.

BOOME—OLIVER.—On July 31st, at St. John-the-Baptist's, Woking, Edward James Boome, M.B., son of James Boome, of Kensington, to Dorothy Arkeoll, daughter of the late Russell Oliver and of Mrs. Russell Oliver, of Grey Walls, Hook Heath, Woking.

CLARK—SYLVESTER.—On July 16th, at St. John's Church, Bulawayo, Rhodesia, William Gladstone Clark, M.A.Cant.Ob., F.R.C.S. England, eldest son of the late James Proctor Clark, to Rubina Elizabeth Jeanette (Ruby) Sylvester, only daughter of Mrs. A. G. Hay and of the late A. J. Sylvester, and stepdaughter of Alexander Graham Hay, of Bulawayo.

KAY—KIDSTON.—On July 31st, at St. Mary Boltons, South Kensington, Charles Wallace Kay, L.R.C.P., L.R.C.S.Edin., L.R.F.P. and S. Glasgow, of Lynton, Hants, only son of Lieut.-Colonel Alfred Goodwyn Kay, R.A.M.C. (retired), to Hamilton Marjorie Bruce Wallace, only daughter of the Rev. John Wallace Kidston, of 6, Priory Grove, The Boltons.

MARSHALL—AINSLIE.—On July 31st, at St. Peter's Church, Peckles, Leigh Richmond Herbert Peter Marshall, M.D., only son of the late Henry Marshall, M.D., F.R.S., of Clifton, to Frances Marion, second daughter of Mr. C. A. Ainslie, J.P., Swinton Bank, Peckles.

Deaths.

BENTHALL.—On August 3rd, suddenly, at Staplake, Starcross, Devon, Winfred Benthall, M.B., late of Derby and Brea'sall, aged 58.

BUCHANAN.—On August 1st, at Kirkgate, Thirsk, Walter Isaac Buchanan, aged 43.

GARDNER.—On August 1st, at The Cottage, Brockenhurst, suddenly, T. Fred Gardner, M.D., M.R.C.P., of The Moynie, Boscombe Spa Road, Bournemouth.

NORTON.—On August 4th, at Reading, after serious operation, Arthur Trehorn Norton, C.B., F.R.C.S., of Layfields Wood, Ashampstead, Berks, aged 71 years.

WALKER.—On July 29th, at Huddleby House, Spilsby, J. West Walker, Esq., M.B., J.P., aged 83.

WHITE.—On August 1st, the result of an accident, Howell H. White, M.B., C.M.Edin., M.R.C.S., of Corwen, N. Wales, aged 60.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

Vol. CXLV.

WEDNESDAY, AUGUST 14, 1912.

No. 7.

NOTES AND COMMENTS.

The Manchester Election Result. DAY by day the influence of the medical profession upon the affairs of civil life appears to be growing steadily. As a collective body, medical men are now more united than ever before, especially with regard to conditions of medical practice as likely to be affected by the National Insurance Act. It is, therefore, a most significant fact that the Unionist candidate for North-West Manchester was returned last week by the substantial majority of 1,202. This complete turn-over from the Liberal cause must have been due, in no small measure, to the united action of the local medical men who issued a determined manifesto against the working of the medical benefits under the Act. No other conclusion can be drawn than that the voice of the profession in a large and important constituency has made itself heard with good effect and has been instrumental in securing the return to Parliament of the man whom they judged the best able to represent their views.

The Phantom Pool. It cannot be said that much headway has been made on the side of the Government during the last few weeks with regard to meeting the just demands of the medical profession on the question of the medical attendance of insured persons under the National Insurance Act. For the sake of doing something, apparently, Mr. Lloyd George has elected to contribute an article to the "Medical Supplement" of the *Nation* upon "The Medical Profession and the Insurance Act," which, upon the face of it, looked promising. Upon a careful perusal of this latest communication of the Chancellor our feelings resembled those of the traveller in the desert who suddenly realises that the refreshing pool from which he had hoped to quench his thirst is but a mirage. The fatal policy of delay and uncertainty on the part of the Government, which led to the final decision of the Liverpool meeting of the British Medical Association, is still persistently adhered to by Mr. Lloyd George, who, while hoping that the machinery of the Act may be "properly used by the profession, with the help of the great multitude of people who sympathise with their desire to improve the conditions of medical service in this kingdom," comes no nearer the removal of the existing *impasse* than in any of his former utterances. The promised regulations, shortly to be published, are, he states, so flexible that all necessary safeguards for the proper conduct of medical practice will be provided. When they appear the medical profession will be able to judge how far they will be able to carry out the duties involved. Meanwhile, no time must be

lost in perfecting the organisation of a public medical service professionally controlled.

An Attack on Hospitals. THE medical profession has always been a favourite butt for malign attacks, while "hospital scandals" are seized upon as prize tit-bits by the sensation-mongers of Fleet Street. The majority of these attempts to injure the reputation of medical men and institutions consist of gross misrepresentations of facts which a little explanation clears up at once. Many of the statements, not intentionally deceptive, when duly analysed, are utterly without foundation, but, since their perpetration only serves to prejudice the unthinking classes against hospitals, it is necessary to point out in what direction these errors lie, so that the true condition shall not be wilfully obscured by avoidable misunderstandings. In the July issue of *Cassell's Magazine* appears an "outspoken" article entitled "The Scandal of our Hospitals," in which the author, whose name (or pseudonym) is unknown to us, makes certain grave charges against the modern hospital, more especially in regard to the methods of giving medical instruction to students and to the treatment of out-patients. We consider it our duty to refer to this article, which is not quite the kind of thing we should have expected to find within the covers of a high-class monthly magazine, in order to correct some of the unpleasant impressions left by its perusal. We pass over such allegations as patients being "the victims of surgical science," "mauled about by incompetent youngsters," and "herded together like cattle in cheerless places to wait the convenience of the little medical gods who condescend to see them—at their leisure."

Fact and Fiction. SUCH shafts of criticism fall harmlessly to the ground and need not be considered seriously. When we go on to read, however, of the number of deaths that are alleged to result from "sheer experiment," that the meanest advantage is taken of poverty, that common ailments are neglected in favour of rare cases, and that economy is practised upon the patients, it is only right that some steps should be taken to verify or disprove the truth of these wholesale assertions. There is a sense, of course, in which every form of medical treatment is an experiment, since there is always some unknown quality to be reckoned with in the patient, but this is a fact the truth of which is difficult for the public to appreciate. As for poverty being taken a mean advantage of, there is not a hospital in the land where the poorest beggar does not receive the same medical and surgical treatment that would be given to a

millionaire in time of vital need, though no one expects dietetic luxuries nor every expensive refinement of synthetic drug-therapy in ordinary hospital practice. As to common maladies being neglected for out-of-the-way diseases, it is the experience of all medical men that it pays best to study everyday and minor complaints most carefully, since these comprise the bulk of the cases met with in general practice. If practical medicine is not to be learned by "living lessons for medical students," it is difficult to see how the knowledge of disease could ever be attained at all. As a matter of fact, patients do not object to being lectured upon, provided that it is not over-done. We agree that a lack of sympathy with human suffering is a deplorable thing, but happily it is not a common trait among those who have spent much time within the walls of a large hospital. It is appropriate, perhaps, that such an article as this, full of rash generalisations and unsubstantiated assertions, appears in a magazine of "fiction."

The Domestic Flea at Home and Abroad.

Now that all the world is on holiday there are certain inevitable experiences appertaining to the sojourning of the traveller in strange abodes. Amongst these is the domestic parasite, the house flea, which is wont to haunt berths on board ship, a certain type of lodging house and the baser kinds of caravanserai. In some countries, such as Spain and Egypt, fleas are universal in their distribution. Some travellers are able to scoff at this little parasite, inasmuch as they are immune to its bite—while in others it causes the greatest physical dread and banishes sleep. Curiously enough, the explanation of this personal vulnerability has not yet been ascertained by modern medical science. On the other hand, scientific medicine has identified the flea as the active agent in the transmission of various infectious maladies, of which plague may be taken as the first discovered and most important. From this point of view the bite of the lodging-house flea assumes another aspect, for in addition to the mere inconvenience of an irritant wheal there is the possibility that the proboscis of that particular insect is charged with the virus of some more or less potent malady. In many other directions the material history of *pulex irritans* is interesting and suggestive.

The Pulex Family at Home.

In the bedroom which represents the wide, wide world of some humble lodging-house flea, it rears its family, which goes through the stages of ovum, larva and pupa, chiefly in the cracks between the boards. As a matter of fact the flea is a model parent and attends faithfully to the nurture of the little white grubs in their home upon the floor. This habitat of the younger generation explains why fleas do not flourish in rooms that are under the care of a vigorous and thorough housewife. Not only is a remorseless war waged against the fleas themselves, but existence is rendered well nigh hopeless for the younger brood, who are scourged out of every snug retreat by soap and water and brushes and beatings of carpets and rugs and so on. The presence of fleas connotes slack and slothful housewifery. That is the last word on the matter. Fortunately, the modern fashion is to have polished and impermeable floors with rugs and carpets that can be frequently aired and cleansed. Perhaps, after all, it is well that the traveller should be reminded of the evils which affect the outside world.

The Recent Celluloid Fire.

It is to be hoped that the fatal celluloid blaze in the City of London—upon which we commented last week—will not be allowed to pass out of recollection after the fashion of a nine days' wonder. Another of the girls who jumped from the roof has died since the main inquest, so that another chance has been afforded to a City jury to express their views upon the general question of celluloid and its dangers in crowded centres of population. Since our last issue several questions have been put to Mr. McKenna, whose answers on behalf of the Home Office have been of an unsatisfactory nature. Surely he could not have read any full report of the City Inquest held by Dr. Waldo, or he would hardly have said there had been no dereliction of duty on the part of the Home Office. He admitted there was a technical fault in the omission of the inspectors to see that the word "exit" was put up. Can he explain why none of the inspectors was informed that No. 21, Moor Lane, one of the largest celluloid factories in the Kingdom, was described under "Christmas Cards," and why not a single factory inspector knew, after a personal visit, that celluloid was used on the premises? Can he say why a register is not kept of celluloid factories? Can he say why Dr. Whitelegge's memorandum of draft advisory regulations was not brought to the attention of Messrs. Angus Thomas or any of their employees at 21, Moor Lane, where the fire took place? Last, but not least, can he inform the public what steps have been taken by the Home Office to carry out their undertaking to maintain the fire exits and other fire precautions provided by the London County Council? It is to be hoped that some Member of Parliament will inform himself as to what took place at the City Inquest, and will insist on something more satisfactory than a whitewashing official answer from the Home Office.

LEADING ARTICLES.

THE RELATIONS OF PRESCRIBER, DISPENSER AND PATIENT.

ACCORDING to the best traditions of medical practice the rule has always been held inviolable which regards as sacred the relations that exist between the physician and his patient. Nothing should occur to mar the confidential sanctity, as well as the sacred confidence, that pertains to the very atmosphere of the consulting-room. Here, at least, the patient should be free to unburden his mind, without let or hindrance, to one who will not only listen sympathetically, but who will keep inviolate his patient's secrets. Neither the officious interference of friends and relatives, however well-meant, much less the intrusion of anything approaching to officialdom (*pace* Mr. Lloyd George), must be allowed to disturb this essential feature of medical consultation. Once this is destroyed, or even weakened, the Hippocratic oath, to which every practitioner worthy of the name has subscribed in spirit, if not in word, becomes as a thing of nought. It is most fervently to be hoped that this peculiar relationship will never be broken as a direct or indirect consequence of the working of the National Insurance Act. If the position of the

prescriber is responsible, no less so is that of the pharmacist, and the relations between these two individuals, in the interest of the patient, are also to be regarded as sacred. In the able and thoughtful paper read before the recent British Pharmaceutical Conference on the mutual relations between the physician, chemist and patient, by Mr. J. Rutherford Hill, Ph.C., the point is rightly insisted on that the dispenser should regard the prescription as a confidential document, and that he should not divulge its contents nor explain the uses of its various ingredients to the patient. It is, of course, as much outside the province of a dispenser as that of a hospital nurse to criticise the prescription as a form of treatment, and we are glad to think that such a thing is extremely rare. In the case of an error of dosage or an incompatibility, chemical or therapeutical or both, in the prescription, it is the plain duty of the dispenser to communicate privately with the prescriber. When the latter is inaccessible and the case is one of urgency, no little responsibility devolves upon the chemist, and he would be, under these special circumstances, perfectly justified in modifying the prescription to the best of his ability and knowledge in the interest of the patient, and he will lose no time in acquainting the physician with the full facts of the case. Needless to say, no indication of any difficulty must appear manifest to the patient. Mr. Hill very properly condemns the practice of the keeping of prescriptions by dispensers for the purpose of recommending them to other persons presumably suffering from the same illness. Similarly, copies of the prescription should not be tendered to the friends of the patient on request, for no practitioner likes to feel that there is even the least possible chance of his professional skill being exploited. The plan of endorsing a prescription with the words "Not to be repeated" has much to commend it. There is no doubt that a greater co-operation between medical practitioners and dispensing chemists and the exercise of mutual tact and forbearance would go far to prevent many of the small frictions which occasionally arise. Mr. Hill's interesting and instructive paper is published in full in the *British and Colonial Druggist*, August 9th, and we are confident that its perusal will be found most profitable to medical men and pharmacists alike.

CURRENT TOPICS.

Lunacy Commissioners' Report.

THE Annual Report of the Commissioners in Lunacy has now been issued. The Report deserves lengthy notice, but it may suffice for the present to state that a searching analysis is given of the incidence of insanity in the sexes. It is affirmed that there are certain conditions in the life history of most insane persons which have had definite relation to the attack that has accompanied or followed them. Of cases in which an insane heredity was considered a foremost factor, the proportion of females was 59 per cent.—considerably

higher than that given on the total admissions. Dr. Mott in his exhaustive inquiry, appended to the Report, into the family histories of inmates of the London County Asylums, points out that among the offspring of insane parents, daughters are much more numerous than sons—viz., in the proportion of 292 to 208. These figures show that the female sex in a stock is more liable to become insane. In cases with a family history of alcoholism, the proportion of females was 53, being two above the mean. In a total of 411 cases the period of puberty and adolescence was specially noted as an important factor, and here again the proclivity was more marked in the female sex (56). Sudden stress was recorded in 35 males as compared with 65 females. Prolonged stress likewise appears to be a more frequent precursor of insanity in females than in males, namely, 45 males to 55 females. Intemperance in alcohol was considered as a principal factor in nearly as many cases as was prolonged mental stress, but here the male cases were more than twice as numerous as the female—namely, 68:32. Syphilis as a chief factor was noted in the proportion of 87 males to 13 females. Injuries were likewise far more common as antecedents in males (80) than in females (20). Amongst other "causal conditions" is influenza, where the female sex slightly predominate (53); epilepsy, where the female percentage (44) was much below the mean; and anæmia, where this was very high (79).

External Hydrotherapy in Tuberculosis.

THE hardening as well as the tonic effect of the daily cold bath, or even of the lukewarm rubbing down of the entire body, is well known to athletes and others who derive benefit from the practice. That the external application of water, under scientific control, may be beneficial in cases of tuberculosis is not so fully recognised. According to Dr. Simon Baruch (a), of New York, the graduated application of cold water does not depress the vital powers, as is sometimes popularly held, but, on the contrary, is capable of influencing for good many cases of phthisis when used in an intelligent manner. He has employed water below the skin temperature as part of the routine treatment of pulmonary tuberculosis for the past forty years, having given over 50,000 treatments. No violent cold douching is employed, and the first stage of the application consists in rubbing the body with water at 90°, drying thoroughly. The temperature of the water is reduced two degrees daily until 60° is reached. Friction and slapping with the hands are employed when the patient is enwrapped by a drip-sheet at 80°. After thorough drying, gentle exercise is taken. Ergographic trainings show that muscular vigour is increased after judicious cold water applications. Dr. Baruch points out that this system of "neurovascular training" is quite "fool-proof," and that it can be carried out equally well in the patient's home as in an institution. One great advantage of external hydrotherapy over more active muscular exercise is that there is no disturbance of the respiratory processes which would prejudice the consumptive.

The Edgar Allen Institute at Sheffield.

THE introduction of the Swedish system of movements and massage as an adjunct to medical and surgical treatment has proved to be of the greatest help in the restoration of muscular tone and the completion of convalescence. Professional masseurs and masseuses are attached permanently to the staff of some of the hospitals, and they are able to render good service in suitable cases. Little has

(a) *Medical Record*, July 27, 1912.

been done, however, to bridge over the gap that exists between the hospital ward or out-patient department and ordinary working life in the case of those who cannot avail themselves of convalescent home treatment. The Edgar Allen Institute, founded at Sheffield last year, is designed to supply this need in the case of that great centre of industry. Through the munificence of the founder the institution has been most expensively equipped with all the latest appliances and apparatus for assisting patients, mostly of the wage-earning class, to return to their work after injuries sooner than they could otherwise do. A great many of the cases treated are referred to the Institute from the various hospitals, whose good work is thus supplemented and confirmed. According to the annual report which was presented the other day at the first annual meeting, the Institute has been most successful, and it is satisfactory to note that it meets with the cordial approval and support of the medical profession in Sheffield. Other large centres might follow this lead with great advantage.

Labour Troubles and the Public Health.

THAT the recent industrial disturbances have not been without their effect upon the public health is evident even to the most casual observer of social matters. Those who have a more intimate acquaintance with the sanitary aspect of strikes know full well the miseries wrought by want of work and the lack of food, especially among the women and children. Occurring at a time of the year when epidemic diarrhoea is rife and when it is most essential that no decomposing food of any kind should be sold, it is a wonder that more illness has not resulted from this deplorable state of affairs. In his annual report of the health of the City of Liverpool during 1911, Dr. E. W. Hope makes special reference to the condition of things last summer in that city, when all the best efforts of a well-organised sanitary staff directed towards the prevention of infantile mortality were greatly upset by the labour troubles, the interference with the food-supply being one of the earliest acts of the strikers. The work of street scavenging, of such vital importance in hot weather, was also hindered, and the accumulation of refuse threatened at one time to be a grave menace to the public health. The natural consequence of these wanton checks to sanitation was an outbreak of infantile diarrhoea which only slowly subsided. In spite of great drawbacks, Dr. Hope is to be congratulated upon the promptitude with which sanitary measures were undertaken, for were it not for the unexpected check of last summer, the death-rate of Liverpool would, doubtless, still continue to show the progressive decline which it has done for a number of years.

Eugenics and Population.

A CORRESPONDENT of the *Times* contributes some suggestive facts based upon a census made by himself of the offspring of relatives, friends, neighbours and acquaintances. These represent that prudent class of the suburban population who generally marry late, go up to London on business every day, and earn from £300 to £1,000 a year. The youngest man on the list is about 35 years of age, the oldest about 55. The result is as follows:—One couple with 8 children, three couples with 6, two with 5, five with 4, seven with 3, twenty-four with 2, sixteen with 1 child only, and twenty-eight with none. Thus 172 people have begotten 141 children, although it has been thought well to allow nine more to cover possible additions to actual families. These figures show a decrease of population of 13 per cent. There must, however, be taken into account

that in this class there would be perhaps one in four who, through death, emigration or celibacy, contribute nothing to the population, whose number should be added to the total of married persons so that the proportion of adults to offspring is as 229 is to 150, or a decrease of 34 per cent. As, however, this decrease in reproduction has required a period of rather over a decade and a half the decrease per decade is more than 34 per cent. It is worthy of note that in only two cases have childless couples resorted to adoption (of relatives). With most of the others parental affection would appear to be satisfied by the adoption of dogs.

The New Milk and Cream Regulations.

On Tuesday in last week, the Local Government Board issued a circular dealing with "The Milk and Cream Regulations, 1912," recently made under the Public Health Act, 1907. The regulations are designed to secure that no preservative shall be added to milk, or to cream containing less than 35 per cent. by weight of milk fat. In the case of cream containing over 35 per cent. of milk fat, the addition of boric acid, borax, or of hydrogen peroxide is not prohibited by the regulations, but is subject to a system of declaration required to be followed by persons dealing with cream for the purpose of human consumption. It is intended that preserved cream shall be differentiated from cream to which no preservative has been added. Further, the addition of any thickening substance to cream or preserved cream is prohibited. The duty of administration has been placed upon those bodies who are local authorities under the Sale of Food and Drugs Acts. These regulations seem very wise as far as they go. From the public health point of view it would be infinitely better if they could be extended to prevent the sale of "dirty" milk, against which at present no effectual administrative powers are available.

Flannelette.

WE have repeatedly drawn attention in these columns to the evils brought about by inaccurate and fallacious trade descriptions of goods. People of intelligence must recognise the fact that the mass of the population obtains its information regarding any article principally through the advertisements thereof; and in all classes of society there is a pathetic belief in the truth of the printed word. Since these things are so, it is the duty of our legislators to see that false assertions, which, taken as true, may have detrimental effects, be eliminated under penalty from advertisements. It has been abundantly proven that many varieties of flannelette described as "safe" are not safe, but deadly. And when we hear that in nine months 133 lives have been lost in the United Kingdom through inflammable flannelette, we heartily endorse the petition for legislation which is to be presented to the Home Secretary by a distinguished company of medical men and others. It is requested that a provision should be added to the Merchandise Marks Act, making it penal to describe as unflammable any material which will not stand certain prescribed tests, and that the nature of these tests should be made public. Such a measure would necessarily help in the evolution of a really safe flannelette and be the means of saving many lives.

Medical Reports on Injured Persons.

A DEPUTATION of the Irish Trades Congress, which waited recently on Mr. Redmond, brought forward a point to which, perhaps, due attention has not been paid by medical men. It is a common

practice for employers generally, and insurance companies in particular, to apply to one of the medical or surgical staff of a hospital for a report on the condition of some patient in whom they are interested. The deputation contended that such reports were often furnished without the knowledge or consent of the injured party. The relationship between the hospital physician and the patient under his care is exactly the same as that between the private practitioner and the patient who pays regularly for attendance. Any practitioner who made a report on a private patient without the knowledge and consent of the latter would rightly feel that he had infringed his position of confidential adviser and been guilty of a breach of professional etiquette. It is natural, therefore, that hospital patients should object strongly to such a procedure where they are concerned, and we are glad to see that due publicity has been given to the matter. On the other hand, we do not believe that such practice has been at all widespread, nor do we think that in those cases in which it has occurred the hospital surgeon has realised that he was acting in any way prejudicial to his patient's interests. Mr. Redmond was asked to support the appointment of a Departmental Committee to inquire into this matter in its relationship to the Workmen's Compensation Act. We are sure, however, that nothing further is necessary than to draw the attention of the members of hospital staffs to the subject.

Death Certificates.

We published in our last issue a forcible paper by Dr. McWalter in favour of having an autopsy in every case of death. Without adopting all the author's arguments, we are in entire accord with his demand. It is true that even the most careful clinician who follows his cases to the *post mortem* table finds innumerable errors of diagnosis. Moreover, he finds numerous points cleared up which were inexplicable from the merely clinical point of view. It is in this way that knowledge grows. From the statistical aspect, we fear it is true that records kept as they are at present are only of use in the most general sense. We do not think that the certificate of the cause of death is so frequently erroneous as Dr. McWalter suggests, but nevertheless, there is little guarantee that it is correct. At best it is a good guess. The cause of death should be made a matter of certainty. The present position is entirely absurd, in that the so-called "death certificate" does not even certify the fact of death. The whole matter of death certification needs reform. The fact of death should be certified by a medical man who has at any rate viewed the body, while the cause of death—if statistics on the point are to be of any use—should be verified by an autopsy.

The Domestic Storage of Food.

ONE of the most important factors in the causation and spread of epidemic diarrhoea in the summer is the lack of proper accommodation for the storage of food, especially in smaller houses and tenement dwellings. The subject was brought up before the Section of Domestic Hygiene at the recent annual meeting of the Royal Sanitary Institute at York, when Miss F. I. Lansdowne, Chief Woman Inspector, Leeds, pointed out that in numbers of flats she had visited the only place where food could be stored was the cupboard by the fire or else in the cellar. It cannot be said that either of these is ideal, under existing conditions, for keeping such food as milk, butter, or meat. Milk, if clean on arrival, is often received

in a jug or basin which is dusty or dirty, or soured from the previous day's supply. It is then frequently set aside anywhere, perhaps on a window-sill or shelf, where it is left uncovered and exposed to the dust and dirt of the house and street. In the course of the discussion, Dr. Collingridge remarked that all the care and attention of the local authorities in the examination of food was often entirely annulled by the arrangements for the storage of food in the house. Where ground-floor accommodation for a pantry cannot be obtained, small portable ventilated larders might well be provided for attachment outside a window, with suitable wire-sieve doors, tightly fitting, to exclude dust, preferably with a north aspect. More attention should be paid by builders of houses to the adequate supply of cool pantries where food may be stored without fear of external contamination.

PERSONAL.

H.M. THE KING has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Dr. Ashley Watson Mackintosh, M.A., M.D., to be Regius Professor of Medicine in the University of Aberdeen, in the place of Professor David White Finlay, resigned.

H.M. THE KING has been graciously pleased to sanction the following promotions in, and appointments to, the Order of the Hospital of St. John of Jerusalem in England (August 5th):—To be Knights of Grace, John William Springthorpe, M.D. (from Hon. Associate), Lieut.-Col. Sir Joseph Fayer, Bart., M.D., F.R.C.S. Edin. (late R.A.M.C.), and Major Charles Alfred Hodgetts, M.D., L.R.C.P., A.M.S. Canada (from Esquire).

DR. PURVES STEWART, M.D., C.M. Edin., F.R.C.P., has been appointed Physician to the Westminster Hospital.

MR. HENRY C. BAZETT, M.B., of Wadham College, Oxford, has been appointed to the Radcliffe Fellowship, 1912.

DR. AGNES F. SAVILL, M.A., M.D., M.R.C.P.I., has been appointed Honorary Physician to the London Skin Hospital, Fitzroy Square.

MR. GODFREY BROOKES DIXON, M.R.C.S., L.R.C.P., L.S.A., has been appointed Principal Sanatorium and Tuberculosis Officer to the City of Birmingham.

DR. ROBERT DONALDSON, M.B., Ch.B. Edin., F.R.C.S. Edin., D.P.H., has been appointed Pathologist and Bacteriologist to the Royal Berkshire Hospital.

MR. W. FITZPATRICK, L.R.C.P. and S. Edin., L.F.P.S. Glasg., of Ashburton, Devon, was presented the other day with a purse of gold and an illuminated address upon the occasion of his retiring from active practice owing to ill-health.

DR. J. BOWEN JONES, of Pontycymmer, S. Wales, was the recipient of a case of surgical instruments and a purse of gold the other day upon the occasion of his leaving the district and as a token of esteem and respect in which he was held by all classes.

MR. J. M. COTTERILL, M.B., F.R.C.S. Edin., has been appointed Consulting Surgeon to the Edinburgh Royal Infirmary. The Managers of the institution at their last meeting recorded their sense of gratitude to him for his valuable services to the Infirmary, and they accepted a portrait of Mr. Cotterill, presented by forty-one of his former Resident Surgeons, to be hung in one of the wards.

A CLINICAL LECTURE

ON

OTHER DISORDERS OF IMPEDED RESPIRATION. (a)

By MAYO COLLIER, M.S.Lond., F.R.C.S.Eng.,

Late President of the British Laryngological, Rhinological and Otological Association; late Professor of Comparative Anatomy and Physiology at the Royal College of Surgeons, England.

GENTLEMEN,—In my last lecture, I had the honour to place before you some results of impeded respiration, more particularly of that part known as the upper respiratory tract, and I drew your attention to the fact that most of the common deformities of the face, upper jaw, teeth and palate were due to this cause. I also proved, I hope to your satisfaction, that the common disfigurement known as asymmetry of the nose could, in most cases, be traced to inequality of the functions of the two openings of the anterior nares, as inlets to inspiration. With your permission, I hope to-day to place before you other disorders and deformities due to impeded respiration.

Now, gentlemen, you may probably think that I have loaded the conscience of respiration with too many sins already, but when I tell you that there is no limit to the functions of respiration, in like manner you may conceive it possible that there is no limit to the ills that follow any impediment to this function. The terms respiration and life are interchangeable. Respiration is the one cardinal feature of life.

There is no life without respiration—no respiration without life. This animate world is a breathing world. Everything alive breathes, and there is no life without breath. Shakespeare puts this self-evident or axiomatic truth in more charming words than I can.

I think I may be excused for repeating them, for evidently the great poet was not only a poet and philosopher but a keen observer of the more common and more beautiful fact of nature.

In the play, "King Richard III.," he makes the Duke of Gloucester, who is bewailing his deformed and undeveloped stature, say:—

"But I, that am not shap'd for sportive tricks,
Nor made to court an am'rous looking-glass;
I, that am rudely stamp'd, and want love's majesty,
To strut before a wanton ambling nymph;
I, that am curtail'd of this fair proportion,
Cheated of feature by dissembling nature,
Deform'd, unfinish'd, sent before my time
Into this *breathing* world, scarce half made up,
And that so lamely and unfashionable,
That dogs bark at me, as I halt by them."

This is indeed a breathing world. And I conceive it to be perfectly correct, if indeed sometimes impolite, to reply to the questions as to what so and so may have died of, to say, "Want of breath."

Now, I think it will not be impolitic of us before we go into the great task of inquiring what are the ailments, disorders and deformities of impeded respiration if we refresh our memories with the many and manifest duties with which this great function is burdened. We can here and now ask ourselves the question:

What are the functions of respiration? and if we know what these are, we have half answered the question of what are the disorders of impeded respiration.

Long before a heart existed in any living individual the world was teeming with life. The heart plays very much a second fiddle to respiration, and but for respiration could not perform its duties for many seconds together. You will know that the act of inspiration assists the right side of the heart to fill itself and the left to empty itself.

When Professor of Comparative Anatomy and Physiology at the Royal College of Surgeons, I delivered

some lectures at the College, and I venture here to state that none of my contentions have been disproved. I pointed out a fact previously unknown: that the pressure in the portal vein was always a negative one.

This truth was obtained from actual experiments many times repeated, and with the same result.

The act of inspiration sucks the blood out of the inferior vena cava and portal veins and, at the same time, by squeezing the abdominal contents, squeezes the blood onwards in the portal circulation. It is the old story, suction and force, acting simultaneously, takes the place of a heart for the circulation of the abdominal contents.

Without this the portal circulation would be at a standstill.

Again, our nutriment is bodily sucked into the tissues by the act of respiration.

Inspiration sucks it in and expiration accelerates the flow of blood in the capillaries, so that they take up more readily the fluids and particles that are passing through the tiny openings and passages in the epithelial coverings or mucous linings, as the case may be.

Without respiration, not one single particle of fluid or solid would pass out of the alimentary canal into the tissues, except by the law of diffusion.

With this fact established, it is clear that individuals of sedentary habits, or those whose dress impedes their respiration, and those who from any reason, nasal obstruction, defective muscle development, or disease, are likely to suffer from indigestion, slow digestion, fermentation, distension, gas formation in the stomach, dilated stomach, and all these and many more ills, simply from the fact that the contents of the stomach have not been properly sucked out and squeezed out by the efficient act of respiration.

A man talks about his liver being congested, of flatulence, of a distended and pendulous belly, of piles, of constipation. What else does he expect? Respiration is capable of carrying on his digestion perfectly, of carrying on his portal circulation perfectly, but he won't use this agency. He prefers to respire only sufficiently to oxidise the blood inefficiently and no more, and then he wants to take drugs as a substitute for respiration.

When you disobey the laws of nature, there is no short cut to health, no sovereign cure, not even a two guinea cure. There are no medicines that will do for you what respiration will do. You are asking the impossible. In most cases medicines are a relic of barbarism, a relic of the old ages, of the time of the medicine man. They are the outward symbol of fraud and deception. They are the weapons of the quack and impostor, the patent medicine man, the man who guarantees to cure anything or everything by pills composed of bread or some similar innocuous substance. "Populus vult decipi."

The public love to take something in the way of medicines. They love to be deceived. Consequently the honest man often fails and rogues prosper.

And, gentlemen, this is all due to the fact that we don't understand a few simple facts about ourselves such as I have related to you.

Now we come to another point, quite as simple and quite as interesting. The part played by the heart in respiration.

If you will take up the morning papers, you will see that a good percentage of the deaths recorded are attributed to heart failure.

(a) Lecture delivered at the London Polyclinic Post-Graduate College.

The poor heart is entitled to stop when its chief motor agent, respiration, is treated so scurvily.

The heart is, I remind you, for all practical purposes, a pump—a double pump, or rather two pumps in series. The auricles count for next to nothing, and the right heart acts with the left and helps it, and the left acts with the right and helps it. Each is dependent on the other for its proper efficiency, two hearts or two pumps are quite requisite, one for the lungs, and one for the rest of the body. The keynote is suction and force. The right heart sucks and then forces, and the left heart sucks and forces.

The forcing of the right heart is linked up with the suction of the left heart.

The right heart forces the blood into the lungs and the left heart sucks it out.

But what would happen if the circulation in the lungs were entrusted to the heart alone?

The many disturbing influences that affect the heart discount its power as a motive agent.

A person in a dead faint would soon be cyanosed but for the guardian angel that ever watches over our good.

Respiration comes to the rescue. The blood can only pass one way and the compression that results from the recoil and collapse of the chest during expiration carries on the circulation quite efficiently.

You know that during a prolonged and serious operation when the heart is scarcely acting at all and the pulse is only flickering, the patient remains alive, and not only alive, but of good colour. This is due to respiration.

Respiration says to the failing heart, "You are tired; let me have a turn," and as long as the heart is moving at all, the circulation is carried on efficiently enough to oxidise the blood and preserve the life of the individual.

I said just now the auricles count for next to nothing. The only part of the auricle of any importance is the auricular appendix. This closes the tricuspid and mitral valves immediately before the systole of the ventricle. Each ventricle fills by the aspiration of its elastic muscle wall, just as an indiarubber ball expands after you have squeezed it. By the dilatation of the ventricle, the parachute-like valves separate from the walls of the ventricle and approximate one another.

Towards the end of the diastole, the auricular appendix suddenly contracts and shoots its contents between the rapidly-closing valves, increasing the pressure on their under surfaces and so closing them.

The heart then has a friend in respiration who can and does help it, at all times, but in case of emergency can practically take its place.

It is quite simple and easy to understand that if the whole work of the circulation is entirely placed upon the shoulders of a weak or enfeebled heart by ignoring the assistance of respiration, it may stop suddenly, as we often find to be the case.

Again I may remind you that in cases of suspended animation from drowning, artificial respiration is not only able to carry on the circulation, but is able to carry on the circulation without the smallest aid from the heart. Respiration then is able and does on occasion take the place of the heart when it fails from any functional cause.

Now let us come to another function of respiration, the oxidation of the constituents that form the heat and maintain the life of the individual. An exactly similar process takes place in the grate when the fire is lit or when a candle burns. Now a fire may burn too quickly or too slowly, and so in the animal economy. The fire may burn too fast from too much oxygen or air, or may burn slowly from too much fuel or not enough oxygen. These conditions are all found in the animal economy. I venture to say that a large percentage of the ills that fall to the lot of mankind are due to the latter condition. Too much fuel, not enough oxygen.

What about gout, with all its attendant tribe of aliases?

Now let us formulate this proposition in simple terms.

Heat production is due to the oxidation of the carbohydrates, hydro-carbons and albumens of the tissues.

Efficient oxidation, as in the fire, results in the formation of CO₂ and water, and in man and other animals urea and small quantities of uric acid and other products. These are the waste products of combustion and are easily got rid of, both in the fire and the human body.

Inefficient oxidation, both in the fire and the human body, leads to the formation of waste products, not volatile and not soluble, and so they remain and act as impediments to further oxidation, and ultimately put out the fire.

Now is not this an exact picture of the gouty and sedentary human fire?

So as not to strain your credulity, I will remind you of a familiar picture you have all seen many times, and one which is the very best object lesson I can place before you of the effect of impeded respiration on the human body—a child or young person suffering from the effects of adenoid vegetations in the post-nasal space, so impeding the inlet of the air or impeding respiration. Look at the picture.

Pale face, with characteristic stupid expression and half-open mouth, listless, lazy and wanting in energy. Cannot give attention to anything for more than a few moments; lolls about, sleeps late in the morning, complains of headache and more or less frequent attacks of bleeding from the nose.

The nose is, more or less, always obstructed, and the individual is constantly using his handkerchief.

There may be, and most often is, deafness, associated or not with running from the ears. In a large percentage of cases there is well-marked amyloid dyspepsia with distension after meals and flatulence.

If you look at the body stripped, you find general anæmia and want of development. The muscles are wasted and flabby. The boy stoops badly, the back is rounded. The scapulæ stand out like two wings, and the shoulders consequently fall forwards. The chest in front is flat and depressed, and the cartilaginous margins of the ribs are often turned outwards. There is often pigeon breast. Now look at his abdomen; it is thin. The liver may be, and often is, enlarged, and the colon is mostly full and distended; in other words, there is chronic constipation. Now turn him round and look at the back.

Rub your finger down the spinous processes of the vertebræ and you will see the red line produced is not straight. There is some degree of lateral curvature of the spine. Now look at his legs and feet. There may be, and often is, some degree of flat foot. The epiphyseal cartilages may be enlarged; the tibia and femur may be bent and the inner condyle of the femur prominent.

There may be then commencing rickets and genu valgum. If you inquire of the mother or nurse, she may tell you the boy has nocturnal incontinence of urine and has had a fit or two.

Now this is not all romance. You know as well, or better than I can tell you, that every one of these symptoms may be present in various combinations when the respiration is impeded by post-nasal growths. Look on the reverse side of the coin.

Remove the post-nasal growths and restore respiration. Treat the defects efficiently and in three to six months, every trouble has vanished, like snow before the sun. It is not a case of *post hoc ergo propter hoc*, it is cause and effect. Even to-day, even in this year of grace 1912, you will find some ignorant and presumptuous persons who say they have been warned by their doctors not to have tonsils as big as duck eggs removed and not to have adenoids removed for fear of some chimerical harm that nobody has ever seen or ever heard of.

Air and light are requisite to all animal and vegetable life, and only the baser forms of life as represented by some germs delight in darkness and foul air.

The protective forces of nature are proof against all the attacks of germs provided the tissues are not vitiated or weakened by auto-intoxication by the forma-

tion of some poison generated in the tissues and as constantly produced as excreted.

Before I finish this lecture, I have brought some original diagrams here illustrating the most important facts of the circulation.

I must give you an illustration. You know the sounds of the heart. There are two in each cycle of events and the first is produced at the mitral and tricuspid orifices, and the second at the semilunar aortic and pulmonary valves.

Will you note I said at the orifices. Now if I canvassed this meeting, I feel sure there are very few here who could give me a correct answer to the question: What are the causes, the essential causes of the first and second sounds of the heart?

All the old notions of the sounds of the heart being due to the sudden closing, like slamming a door, of the valves, were childish and indefensible nonsense and founded on ignorance of the commoner laws governing the movements of fluids in closed canals or tubes under pressure.

The very idea of a back current in the aorta was ridiculous; you can only get a backwash in liquids where gas or air is floating on them. As a matter of fact, all the valves close quite gently. The last drop of blood that enters the aorta or ventricle remains at the point of apposition of the three or two valves as the case may be. At the moment when the last drop of blood has entered the aorta or ventricle, the pressure above and below the valves is equal.

The moment when the ventricle begins to contract, a sudden great pressure is thrown upon the under aspect of the tricuspid and mitral valves and the pressure above is entirely relaxed.

The same at the aortic orifice, but later.

The moment of commencing diastole of the ventricle, the pressure on the upper surfaces of the valves is great and there is no support below rather a negative or minus pressure from the active dilatation of the ventricle. This then is the cause of the two sounds of the heart, sudden stretching of the valves from sudden loss of support on the auricular and ventricular surfaces respectively resulting in a sound that may be exactly imitated by suddenly stretching a piece of cotton or silk handkerchief laterally, when the same sound is produced.

Now another point. You know the sinuses of Valsalva. Well, Valsalva first described them, and naturally wanted to know what they were for.

Of course, the ridiculous theory of a backwash that closed the valves was made use of, and this backwash was reflected outwards on to the walls of the aorta and formed these bulges by pure wear and tear, so that if a man only lived long enough, he would have three bulges as big as an orange or a football at the root of his aorta or, in other words, three aneurysms.

If you went to an engineer and asked him to make you a valve like the semilunar he would be bound to put a bulge there to ensure that the valve could not line the wall of the circular aortic tube. If it did you could not get it down again when once thrown up. The pressure would be always on its under surface. Then, again, another point. The function of the auricular appendix. We have been treated to all sorts of romances about the functions of these cocked hat like portions of the auricles with the wonderful provision for some great effort, as shown by the powerful ribs or rows of muscle fibres in the interior, the *musculi pectinati*.

Now I have watched these structures at work for hours, and I have watched the auricle as a whole, and the great veins at work and had a manometer in the body of the auricle all the time. The only part of the auricle that contracts forcibly is the auricular appendix and its function is seeing that it is situated immediately above the mitral and tricuspid orifice, to shoot its contents into the ventricle, to close the tricuspid and mitral valves previous to the systole of the ventricles. Without these (by some termed useless ornaments or appendices) regurgitation

would take place into each auricle on contraction of the ventricle.

Just one word more, and then I have done.

The pulse has been the cause of much speculation. I can quite understand that many of the theories regarding the pulse have arisen from the notion prevalent with the earliest anatomists, that the arteries contained air. The arteries were always found open and empty when cut across in the cadaver and nothing was easier than to talk about a wave of blood passing along an empty tube. Unfortunately for this theory, the arteries are always full and over-distended and the blood is under considerable pressure, and any given particle of blood can only be displaced or pushed on by the particle next to it, and this by the one next to it and so on *ad infinitum*. It is much the same as if the aorta was filled with minute marbles.

When the ventricle contracts it would shoot its contents into the centre of the first few inches of the elastic aorta and distend only this part. The valves being closed, the reaction of the aorta would distend another section and so on to the smallest capillaries.

The pulse then is due to the distension of the aorta by the ventricle and the reaction of the elastic tube distending section after section of the artery to its finest ramifications.

This causes the appearance and feel of a wave passing from the heart to the periphery.

I end my lecture by advising you, as the Ancients did: *γνοε σεαυτον*—Know thyself.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Pierre Lereboullet, *Médecin des Hôpitaux de Paris*. Subject: "The Treatment of Biliary Vesicular Colic."

ORIGINAL PAPERS.

EPIDEMIC GASTRO-ENTERITIS.

By H. L. MACCARTHY, M.A., M.D., D.P.H.,
Late Assistant Medical Officer, Park Hospital for Children,
Lewisham S.E.

Few features of urban mortality have received from sanitary experts more studious attention than the annual recurrence, with varying intensity, of epidemic gastro-enteritis in infants and young children.

Bacteriological investigation has shown that the disease is invariably associated with the presence of micro-organisms, but it is not now seriously maintained that any one form of organism is specific. With existing knowledge it seems probable that there are many varieties of organisms which, in favourable circumstances, may multiply in the gastro-intestinal tract and produce toxins capable of giving rise to the diarrhoea and other features associated with the disease.

Undoubtedly the nature of the child's food is of supreme importance. Holt (1) found only 3 per cent. of breast-fed infants amongst nearly 2,000 cases of fatal diarrhoea. It is known that an average sample of milk, as delivered to the urban consumer, contains nearly four millions of micro-organisms per c.c., and that in summer this figure is often greatly exceeded. Apart from the fact that milk forms such an admirable nutrient soil for the development and multiplication of bacterial life, other factors are considered of importance in relation to the great frequency of gastro-enteric disease among bottle-fed children. The tendency of recent research has been to emphasise the differences in the relative absorbability of the albumens of the two kinds of milk. It has also been suggested that the disease often results from a disturbance of balance between food elements taken into the alimentary tract and food requirements, not only in regard to quantity, but more particularly in regard to the relationship of individual constituents. Any disturbance of balance among the food elements prevents

assimilation and allows bacterial action to begin, with consequent decomposition and absorption of toxins. Thus Finkelstein and Myer (2) succeeded in causing diarrhoeal disorders in healthy children by increasing the salts and sugars, and attributed this result to the fat in presence of an excess of salts and sugar.

Another view is that the diarrhoea is merely a symptom of the defence reaction of the organism, and is caused by the irritation of the intestinal mucosa by the acids resulting from the decomposition of the fat or carbohydrate of milk by bacteria, such decomposition taking place almost wholly prior to administration. This theory is based upon the experimental work of Bokai, published in 1898, which showed that various acids resulting from food decomposition can produce not only diarrhoea in animals, but in small doses a catarrh of the intestinal mucosa, and in large doses even inflammatory changes. As lactic acid is harmless to the infants' intestine, the pathogenic properties must be associated with the acids arising from the decomposition of the fat.

The marked prevalence of gastro-enteritis in the third quarter of the year is to be attributed to the influences which then favour the multiplication and distribution of bacterial life. It is also probable that the constitutional depression produced by a persistently high atmospheric temperature interferes to some extent with normal digestion. The mucous membrane is thereby weakened, causing it readily to become inflamed by undigested food, which acts as a foreign body, and a way is thus prepared for local intestinal infection.

The characteristic features of this disease consist in sudden onset, attended by frequent vomiting, frequent motions of loose, watery consistency, which, in the early stage, contain neither mucus nor blood, are green in colour and not offensive. A condition of collapse ensues, so that the extremities are cold and cyanosed, the eyes sunken, the skin shrivelled, and the abdomen generally lax and retracted; the pulse is feeble and small, and the temperature is raised.

Among 109 cases admitted to the Park Hospital in the autumn of 1911, 46 presented the features above described. Of these 27 recovered and 19 died. Of the 19, two groups stand out sharply. There are those which die in a few hours or days after the onset of symptoms. Four died within twelve hours of admission. Five lived from four to ten days and died from hyperæmia, convulsions, or cardiac failure. In none of these was any lesion found that would directly account for death. The second group are those which recover from the acute symptoms but subsequently waste away in spite of all treatment and care; it is a class which is but little understood. No fewer than seven ran this protracted course and died without macroscopic evidence of organic disease; most of these lived four or five weeks after the acute attack, and one for nine weeks. It may be that the digestive organs in these cases are so impaired from the severity of the attack that little or no food can be assimilated.

It is usual to give a very grave prognosis in gastro-enteritis. Yet it is probable that, in the great majority of instances, death does not result from an acute attack in a previously healthy child. As a rule the infant who dies of gastro-enteric disease has suffered from malnutrition for a longer or shorter period before its fatal illness began. Careful investigation will almost invariably show that the acute process has developed upon a soil which has been long prepared for it.

This malnutrition may be due to any influence that diminishes vitality, whether acting after birth or during intrauterine life; it may be, and very often is, due to impure air, inadequate clothing, or neglect of other hygienic precautions; it may occur in breast-fed infants from too frequent or over-feeding, or from abnormal breast milk; but it is more commonly due to the chronic digestive troubles of bottle-fed babies, and these in turn are caused by food, improper in amount or time of administration.

The treatment of gastro-enteritis may be prophylactic or curative, the former being infinitely the more

important. It cannot be too strongly insisted that the breast-feeding of infants, in conjunction with ordinary hygienic precautions, is far the most effective means of preventing the onset of the disease. Yet we have to recognise that this is impossible in many cases, through economic or other causes, and that recourse must be had to artificial feeding in some form. The cheapness and availability of cows' milk combine to make it the substitute in common use. Unfortunately, it is in this source that most epidemics of gastro-enteritis have their origin. As withdrawn from the udder, milk is sterile, and opinions differ as to the usual place where contamination occurs. Delépine concluded from experimental work that it occurred most frequently at the farm or during transit. Newsholme, however, showed that at Brighton 53 per cent. of fatal cases must have been infected at home, and believed that the milk had been exposed to infected dust in the house. It is now recognised that flies constitute a further important agency in the carriage of infection.

Many public bodies endeavour to ensure the purity of the milk supply during summer by affording facilities for its sterilisation. Such measures, where carefully carried out, have effected a considerable reduction in the infant mortality, for they inevitably destroy any pathogenic organisms present in milk, though not necessarily destroying any toxins which these may have elaborated.

The great difficulty in practice has been that of educating the laity as to the importance of giving proper care to the preparation and preservation of their infants' food. It is very difficult to get the average mother of the poorer classes to realise the dangers arising from lack of scrupulous cleanliness of bottles, spoons, soothers, etc.; the importance of prompt attention to all mild derangements in summer; and that a deduction in the amount of food and an increase in the amount of water is a good summer rule. The ideal method, in the case of children who are bottle-fed, is that the milk should be obtained fresh at least twice a day, sterilised at once, covered in order to prevent access of dust and flies, and kept in a cool, light place.

At the Park Hospital during the summer and autumn of 1911 both sterilised milk and desiccated milk were extensively used, the latter being reconstituted by the addition of water. Dried milk possesses obvious advantages over raw milk, in that it is not liable to contamination by micro-organisms, whether dust-borne or by flies; it keeps perfectly during the warmest weather, and can be freshly prepared for each meal. In a series of 137 cases, 74 were fed on sterilised milk for several weeks before their illness, the remaining 63 on dried milk. Of the former, 8.1 per cent. died; of the latter, 4.7 per cent. The readiness with which dried milk is digested is probably due to the fact that, in the process of drying, the casein undergoes some physical alteration which prevents it subsequently forming a dense clot. Such results as we have thus far obtained seem to indicate that the use of sterilised milk over long periods tends to lower the resistance to disease. The mineral matter in dried milk consists largely of calcium in a readily assimilable form, and this, by maintaining the normal specific gravity of the blood, may be of considerable value in preventing gastro-enteritis—for investigation has shown that the onset of this disease invariably coincides with a diminution in the blood's specific gravity. Moreover, the acidity of dried milk is only plus 4.5 (Eyre's scale) as compared with plus 22.6, which is that of an average sample of milk in summer. This may also be a factor of some significance. It is usually objected that the use of dried milks is associated with tendencies to rickets and scurvy, but we have not experienced any difficulties of this kind, even in cases where feeding has been continued over long periods. The particular form we have used is simply a dried essence of whole milk, with additional cream and milk sugar, a close approximation to dried human milk being thus attained. It has been employed in the control of epidemics

during the past few years by the municipal authorities of Finsbury, Leicester and Sheffield. (3)

Obviously, if any substitute for ordinary milk in summer is to be extensively used, the economic factor becomes of paramount importance. At the Park Hospital and other institutions, dried milk was found to be relatively cheaper than raw milk. If there were an organisation whereby municipal authorities would come into direct touch with the consumer, the general public could doubtless obtain similar advantages.

In the curative treatment of gastro-enteritis, the rectification of bad hygienic surroundings and the dietetic treatment are of fundamental importance. Milk in any form must be at once stopped for 24 hours or longer, according to the severity of the case. Thirst should be relieved by bland fluids, frequently given, but in small quantities, and always cold. For this purpose barley-water, rice-water or whey are satisfactory. The use of albumen-water results in intestinal putrefaction, unless given in too small quantity to be of nutritive value; it is too good a culture medium for bacteria. It is advisable, if there is persistent vomiting, to administer copious draughts of cold water, previously boiled. This is readily taken, and may be almost immediately vomited; this cleanses the stomach, and it is a fair substitute for washing it out. It also helps to wash out the small intestine, and this should be further assisted by the administration of *ol. ricini* (5i-5ii); when this cannot be tolerated, ealomal is the best substitute, and may also be given in minute doses as an intestinal antiseptic every three hours during the first 36 hours. In my experience the various bismuth and tannin preparations are entirely without value. Should heart failure supervene, *strophanthus*, caffeine and camphor have their uses.

In conditions of extreme collapse, half a minim of *Liq. Strych. B.P.* may be given every four hours. The subcutaneous transfusion of 4 ozs. of normal saline solution at 100 deg. F. is a valuable adjunct in many cases, in conjunction with rectal irrigation, once in 24 hours, with 6 to 8 ozs. of hot water, this being continued until the returning fluid is clear of mucus. In all severe cases, brandy is preferable to any other stimulant, 10 to 20 minims being given every two hours in the barley-water.

The best guide for resuming milk diet is the general condition of the patient rather than the temperature or any one symptom. At first, any mixture employed should be poor in fat and carbohydrates, given in the smallest amounts and with long feeding intervals. Digestion being greatly impaired, any increase in concentration of food should be gradual and the result carefully watched.

It is clear that the problem of infant mortality must be solved in the tenements. By reason of large numbers and gross ignorance the vast majority of deaths occur here. Many difficulties will have to be met before the hope can be entertained that gastro-enteritis will be controlled by sanitary authorities. The questions of poverty, bad housing and alcoholism cannot be materially influenced within a decade. On the other hand, it is a significant fact that the infant mortality is highest in those countries in which illiteracy among the women is greatest. The colossal ignorance of the poor in questions of infant feeding and hygiene can be immediately dealt with. In no department of medicine are proper measures more likely to be followed by rapid and striking results than in the reduction of the infant mortality.

SIR CARL MEYER will preside at the annual festival dinner of the City of London Hospital for Diseases of the Chest, Victoria Park, which will be held in the Hall of the Worshipful Company of Fishmongers, by kind permission of their Court, on Thursday November 21st.

THE INFLUENCE OF SEGREGATION UPON PROSTITUTION AND UPON THE PUBLIC.

By HOWARD A. KELLY, M.D.,

Professor of Gynæcology, Johns Hopkins University.

So many are the sources and so numerous are the ramifications of what is called by dishonourable pre-eminence "the social evil" that we must of necessity confine our examination to a single phase of it, namely, segregation, or the setting apart of a certain section of the city to an immoral business, under governmental sanction and control, with a view to checking its growth and rendering it safer for its patrons.

There would seem to be but three alternatives worthy of consideration in dealing with prostitution, namely:

1. Segregation, with or without legalisation.
2. Indifference, *i.e.*, letting the matter thrive without interference.
3. An active, unremitting crusade, with extermination as its final objective.

The second alternative—indifference—resulting in late years in the development of prostitution into a commercialised business involving seductions and graft on a vast scale, is the only one which has really been tried in this country.

Indifference has been the attitude of the public; while the police and our judges have often insisted upon some degree of segregation. Segregation has, moreover, been a measure adopted and maintained by those most interested, the brothel-keepers, for mutual support and to avoid too great publicity.

The meetings of three international Congresses at Brussels and Madrid, other public meetings like this held all over the country, the formation of numerous societies and commissions of investigation in our large cities, as well as the many successful prosecutions of panderers and bawdy-house keepers, these things all testify to a public conscience awakened to the realisation that the policy of indifference or of quasi-regulation is ruinous to the body politic, and brands with infamy every community in which it is permitted to continue when once the facts are known.

Our entire country has agreed to dismiss this alternative as one only tolerable in a state of ignorance of the facts. We will, therefore, confine our attention to (1) Segregation, embracing, as it always does, certain forms of legalisation, and to (2) Extermination.

Segregation appeals at once and irresistibly to the average man as the most acceptable plan, when he for the first time approaches the subject, because:

1. It recognises the fact that the evil is as old as the race, and appears, therefore, ineradicable. Segregation devotes every energy to curbing it.
2. It is a method or policy which has been tried extensively in Europe for over a century.

3. (A most potent reason.) It rids the individual of the necessity of bothering further with the matter, by relegating the control of prostitution to a set of qualified officers of the law. This is the attitude so familiar to us all some twenty or thirty years ago. Since that time, in every land, vice has increased enormously; it has taken on new forms in America, copying the worst European prototypes, and its baleful influences have been felt in thousands of new channels.

Any and every definite policy of segregation involves the recognition of prostitution by the law, the investing of certain officials with due authority to control, and the giving to prostitution the status of a legitimate trade. It at once necessitates the employment of a special body of police exercising surveillance in order to keep prostitution and the prostitute within assigned bounds and in order to repress its ever-recurring criminal manifestations. Segregation calls also for the official enlistment and the recognition of a need of the services of certain members of the medical profession who regularly and at intervals of a few days examine the prostitutes in order to certify that they are free from disease and therefore safe, or to set apart the diseased ones for treatment. Furthermore, it must at least contemplate an acquiescence in the necessary efforts to procure the requisite fresh supply of young

women, often virgins, many thousands each year, to fill the places of those dying of disease, by suicide, or thrust out of the door when worn out to enter almshouses or asylums. It also necessitates the provision of adequate hospital accommodation for the multitude of women and men afflicted with those loathsome and highly contagious diseases, syphilis and gonorrhoea.

If I knew of a single argument in favour of segregation, or if I had met with any good results in the shape of an improvement through its means, of the morals of a community in any quarter of the world, or any lessening of disease by its beneficent ministrations, I would place them before you now. I know of none. I do not believe there are any. I have, therefore, come here to-night (a) to ask each one of you, individually and personally, to stand in line with the most modern advancement in social progress—namely, that of opposing segregation and regulation of vice, because it has been thoroughly tried and demonstrated to be a failure in all the foreign countries in which it has been inaugurated, and in which the system of police control has been far more favourable because far more perfect and less corruptible than in any part of the United States.

I discover that the failure of segregation is admitted by every earnest and pure-minded man and every earnest woman who has made an unbiassed investigation into the matter. Even those whose duty it has been to see it carried out declare the measure a failure. The most earnest advocates of extermination to-day are those who began their inquiries under the strong conviction that segregation was both necessary and feasible.

Let us now begin our inquiry by considering the actual experiences of other countries. Following these conclusive data, I will give you certain authoritative opinions based thereupon. These two lines of argument ought to be convincing and to determine our own judgment and our practice. At least they should prevent us from attempting foolish, already worn-out experiments in such a vital matter, and enable us to avoid that common American pitfall, viz., the taking up of ancient, worked-out problems with which we proceeded to deal as though they had never been propounded before, and as though it devolved upon us to illuminate the world by their solution.

I quote the following from Prof. Seligman, who tells us that "the system of regulation in Brussels was long considered a model. At the end of the seventies a series of most outrageous scandals occurred, showing an astounding condition of corruption among police officials and direct complicity between the chief-of-police and the houses of ill-fame. These revelations, which confounded all Europe, somewhat abated the zeal of the enthusiasts for the Brussels system."

At the second international conference, held in Brussels in 1902, the abolition movement was headed by four leading Paris doctors—Dr. Gailleton, the head of the French Delegation; Dr. Gaucher, the successor of Prof. Fournier; Dr. Queyrat, the head of one of the leading hospitals, and Dr. Landouzy, who represented the French Ministry of Public Instruction. These physicians condemned the existing system as utterly worthless.

Although the Abolitionists in France were originally in the minority, the force of the arguments and facts presented by them was such that at the end of its deliberations the Commission voted by a considerable majority that the entire system of regulation, as practised in France, was so defective and, on the whole, immoral that it ought to be entirely abandoned. Thus, after an experience of more than a century, the French experts came to the conclusion that the whole "Régime des Mœurs" had outlived its usefulness.

Professor Seligman also shows that in Germany excellent constructive work has been accomplished by the Society for the Prevention of Venereal Diseases, founded in 1902. Far better facilities have been provided for venereal patients, chairs for the teaching of venerology have been established in the universities,

courses have been provided in sex pedagogy in the high schools, and millions of leaflets have been issued to enlighten the public as to its danger. The result has been a complete change of front in the attitude of the periodicals and the daily press on the subject. Berlin no longer has any open public houses of prostitution, and has no segregated districts. The prostitutes are, however, still registered and compelled to submit to medical control.

In Sweden the change of opinion has been scarcely less marked than in France. In 1903, after the second Brussels Conference, Mr. Otto Westenberg and Mr. Hugo Tamm, who had been converted to Abolitionism, persuaded the Swedish Parliament to ask the King to appoint a Royal Commission to study the subject. The Commission was formed with nine members, seven of whom were Regulationists. During the course of the discussion, however, all seven were converted to the other side. After several years' work, the Commission made its report in 1901. The members unanimously agreed in recommending the abandonment of the existing system of regulation, while their constructive recommendations included the compulsory notification of venereal disease, and the subjection of confirmed prostitutes to the provisions of the law governing vagrants.

In Norway and Sweden the *police des mœurs* has been abolished, and while some of its power has been transferred to the ordinary police, the provision with reference to compulsory treatment has become a dead letter.

"In Italy a complete system of gratuitous dispensary treatment of all venereal patients was developed in the 'eighties and the 'nineties, and paved the way for the abolition of the entire system of police control over women. In 1904 the system was rescinded by administrative ordinance on the ground that 'every sort of direct compulsion for the ascertainment and cure of venereal disease is injurious to public prophylaxis, as it increases the number of persons compelled to conceal their malady and avoid the means of cure.' But some features of the old system are preserved in the Regolamento sul Meretricio in houses of ill-fame, in that the Government still recognises and tolerates these houses. The inmates, however, are entirely free to leave at any time."

Even in Japan, where the celebrated segregated quarter, Yoshiwara, was destroyed by fire a year ago, a movement has been inaugurated with the cooperation of no less important a personage than ex-Premier Count Okuma, to abolish the system of government regulation. A new society, the Kakusei Kai, is now vigorously at work, and is publishing its own journal.

Thus, slowly, but surely, breaches are being made in the solid ranks of those who, until a generation ago, had no doubt as to the effectiveness and beneficence of the regulation of vice. The practice has been given up in Denmark, except in three provinces. Even Madrid has now the same system as Berlin, and no longer tolerates or recognises an area of segregation.

At this juncture, let me cite the testimony of several authorities whose names will count for much in a decision. First of all I would consult one of my *confrères*, Chanfleury van Ijsselstein, who wrote a remarkable pamphlet, as far back as 1889, giving with absolute frankness his experience in investigating the methods of control in use in Paris and Brussels, and his own personal later experience at The Hague, where he was made responsible for the health of the prostitutes. That he was subject to no bias is evident from his declaration that the effort to secure healthy coitus for the public is akin to the question of the purity of the food and drink supply. I quote, *passim*, from his instructive pamphlet:—

"Some years ago I went to Paris and to Brussels for the special purpose of studying this question as thoroughly as possible. These two cities had, at that time, the reputation of carrying out the method of official control and treatment of prostitutes in the best possible manner.

"I had opportunities to observe the examination of prostitutes at the Bureau des Mœurs in Paris and of

(a) Feb. 28th, 1912. Pennsylvania Society for the Prevention of Social Disease, Philadelphia.

following attentively the methods employed by the medical men. I was also present during the examinations at the public brothels, and I feel it right to say that a large number of women were examined in a manner so superficial that I was astonished. On returning from my tour of inspection, I made no delay in seeking an opportunity of applying the knowledge I had just acquired, and I was placed in charge of the examinations at The Hague. I applied myself courageously to my task, with all the ardour of a young practitioner who sees a new career opening before him, and whose zeal is stimulated by the feeling that an important branch of public hygiene is committed to his care. There was at that time no opposition to the application of energetic measures.

"And what were the results of these examinations, conducted, as they were, with the utmost severity? They were so far from satisfactory that at the end of several years I became convinced that I ought to ask to be relieved from an undertaking which was apparently entirely wanting in the usefulness to the public health expected from it in the beginning. How are these negative results to be explained? By the fact that a medical examination, no matter how carefully conducted, affords no guarantee whatever against contagion. In the course of my unexpected visits to brothels I was obliged to send some two-thirds of the women examined to hospitals.

"Moreover, the severe measures which had been taken aroused the whole body of prostitutes to resistance, and I could not make my evening visit to the hospital without a police escort, so much reason was there to fear that the numerous anonymous threats addressed to me would be put into execution. It should once more be noted that at this period the contagiousness of syphilis through the blood and secretions of a patient in the condylomatous stage was not yet demonstrated. A knowledge of this fact would have led me to withdraw a much larger number of suspected persons.

"From all that has been said I feel myself justified in drawing the conclusion that such a thing as a safe public prostitute does not exist.

"A great many men who are kept away from brothels by fear of contagion resort freely to them if this dread is removed, believing that they can profit by such a favourable opportunity with security. I saw clearly, when at The Hague, that the attendance at the public houses increased as soon as the report spread that I was in charge of the examinations. Therefore, the numbers only increased, instead of diminishing, in consequence of the elimination of so many unsafe subjects. And yet, in spite of the minuteress with which the examinations were made, a certain number of persons who had remained abstinent up to that time contracted venereal disease.

"Clandestine prostitution has always been the great obstacle to the adjustment of regulation. With public prostitution, on the contrary, things are quite different. Women who practise it are at the disposition of every corner at any time; their houses are veritable dens of debauchery, where liquor is employed, as a matter of course, to destroy men's will power and drive them to commit irreparable sins. Lastly, does not observation teach us that venereal patients who present themselves at clinics or at public hospitals have most frequently contracted disease through frequenting public houses of prostitution? What I have already said seems to me sufficient to prove that the suppression of public prostitution would, on the whole, be a benefit to public health. If we wish to contend with this terrible class of diseases, it is above all necessary that venereal patients should have medical attendance at their disposal."

During the nineties a distinguished Belgian specialist, Dr. Dubois Havenith, organised a conference, which was held in Brussels, under the presidency of the Belgian Minister of Health and the Burgomaster of Brussels, and 295 of those present were distinguished physicians. It was most significant that, after the conference, some of the most prominent Continental as well as English physicians utterly denied the value of regulation. Three out of the first four speakers, Dr. Blaschko of Berlin, Augagneur of Lyons,

and Barthelemy, one of the medical chiefs of the St Lazare, condemned the existing system. (Seligman.)

Fournier, the greatest syphilographer living, after years of practical experience in charge of the whole system in Paris, acknowledge the utter failure of regulation: "In spite of all efforts at regulation, venereal diseases abound and superabound." Our own Prince A. Morrow is utterly opposed to any form of regulation. ("Social Hygiene and Marriage," p. 342.) Neisser, our greatest living authority on gonorrhœa, and the discoverer of the germ which caused it, is strong in his opposition to segregation and regulation. He says: "One thing is certain, everyone agrees—the partisans of regulation not excepted—that the methods actually in use for diminishing the evils of prostitution cannot be considered effective. The organisation and administration of the surveillance, medical and police, are so defective that, in our opinion, but little is to be expected from it." ("Bull. de la Soc. Internat. de Prophylaxie Sanitaire et Morale," I., i.), and "The system of supervision and regulation of vice which exists is more designed to force into the depths the girls who are on the downward path, and to retain in the profession of prostitution those who are already under police control, than to lighten their return to the right." (Neisser, Conference Internat. Brussels, 1899.) The effect of regulation simply means that the woman is more likely longer to remain a prostitute. (Yves Guyot, "La Prostitution.")

"Inscription upon the register of the bureau of morals is the final stage of vice, the final term of degradation. It is the official formality, which, like the *licentia stupri* of the Romans, regulates and legitimates the sad trade of prostitution. It is, in a word, that sinister act which severs a woman from society and makes her a chattel of the Administration." (Dr. Hippolyte Mireure, "La Prostitution à Marseilles.") "The more regulated prostitution there is in a country, the more prostitution of every kind will develop. And where there is regulated prostitution there is late marriage and the growth of population descends to a minimum." (Armand Déprès, "La Prostitution en France.")

Clifford G. Roe (a member of the National Vigilance Committee, and President of the American Alliance for the Protection of the White Slave Traffic), former Assistant States Attorney of Chicago, for a long time engaged in investigating these conditions, and the writer of a remarkable work, "Panderers and their White Slaves," declares himself, as the result of his investigations, as utterly opposed to all forms of segregation and in favour of extermination.

Dr. O. E. Janney, who has most carefully studied the subject and is widely known as an authority, has written a book, "The White Slave Traffic in America" (published by the National Vigilance Committee), in which he devotes his whole energy to opposing both the system of indifference to which we have grown accustomed and the system of regulation which has so conspicuously failed abroad.

Professor Seligman says, "There is only one point I should like to emphasise, as leading up to the position which I take—and, I may say in this respect, it is the position which, so far as I know, is taken to-day by all the surviving members of the Committee of Fifteen. It is a remarkable fact, that when we came together to investigate the problem, knowing very little about it—just about as much or as little as does the ordinary man or woman—the great majority of us were in favour of regulation on the principle that it could do no harm and might do some good. It was only after a prolonged study of the situation as regards both the facts and the principles involved—that the committee came unanimously to the conclusion that regulation or re-plementation was inadvisable and inadmissible."

Jane Addams, in a series of remarkable articles, (a) portrays the depths of vice and crime to which we, the American people, have descended under the existing conditions of tacit consent and indifference.

The Vice Commission of Chicago issued a report in 1911, covering 368 pages, which seems destined to

(a) "A New Conscience and an Ancient Evil." *McClure's Magazine*. 1911-1912.

occupy a most important place in the history of this subject.

The conclusions of this commission are unassailable because of the independent and representative character of the men and women who composed it, as well as on account of the thoroughness with which the work was done, and the frank fearlessness with which their conclusions are presented. The report breathes throughout an atmosphere of moral vigour, too often lacking in the timorous lukewarm statements to which we have grown accustomed from committees of good citizens.

At the very outset (p. 17), in its "Introduction and Summary," this report declares in bold capitals:—

"Persistent Repression of Prostitution the Immediate Method; Absolute Annihilation the Ultimate Ideal," (b) and "That there must be constant repression of this curse on human society is the conclusion of the commission after months of exhaustive study and investigation—a study which has included the academic with the practical, moral ideals with human weaknesses, honesty of administration with corruption, the possible with the impossible. It has sought to meet all questions fairly; it has made every effort to work with intelligence; it has kept constantly in mind that to offer a contribution of any value such an offering must be, first, moral; second, reasonable and practical; third, possible under the constitutional powers of our courts; fourth, that which will square with the public conscience of the American people."

In a report by the Vice Commission of Fifteen of Minneapolis, issued to Mayor Hayne, last year (1911), the conclusion is stated in these words: "And now, your Honour, the large and exacting task of your commission is at an end. That the work is imperfect, no one can more fully realise than the members of this body themselves; we believe, however, that the main position, Enforcement of Law Against Public Prostitution, is unassailable. We shall be glad of all criticism that is not merely captious or that does not bear the suspicion of a financial interest in the policy of segregation."

Let me then state the case against segregation. Segregation does not, never has and never can thoroughly segregate. The little handful of women under inspection in a given community is but an index of the army of clandestine prostitutes. The futility of all efforts to segregate effectually is shown by the following official figures for three large European cities, where there is a registration list averaging about 10 per cent. of the whole number:

Paris—Police estimate, 45,000; registered, 6,000.

Vienna—Police estimate, 30,000; registered, 3,063.

Berlin—Police estimate, 30,000; registered, 2,016.

Segregation does not protect the public, both because of the inefficiency of the medical examinations, which under any and every political system have at once become farcical and subject to corruption and graft, and because of the false confidence of safety instilled into the boys and men.

Dr. Frederic Griffith, writing of his observations in Paris, states that he has known 400 women examined in an hour and a half! ("New York Medical Record," April, 1904.)

In Berlin the Wassermann reaction has shown that after the lapse of one year almost 100 per cent. of the prostitutes have syphilis; note also that it is not possible to distinguish sharply between the infective and the non-infective stages of the disease.

Segregation is intolerable because it corrupts the police officials who have any dealings with the houses by putting into their hands unlimited opportunities for blackmail and graft.

Segregation introduces a plague spot of vice where violence, debauchery and wild orgies nightly run their gamut of crime, often even including murder, unchecked.

Under a system of segregation a man hungry with lust is never satisfied, while seduction and the violation of virgins outside the segregated districts is far commoner than under repression. The encouragement

(b) Two years ago there were as many prostitutes in Chicago as in New York.

of vice which is thus tolerated in one section of a city can never be confined to that section. The man who enters the segregated district for an immoral purpose carries his immorality and his physical disease wherever he goes, so pervasive and so infectious are these deadly moral and physical miasms. Their diffusion is perfectly demonstrated in the universality of the diseases which are the fateful messengers from the prostitute to her sisters outside of the district.

One capital reason why segregation fails is that it is not even meant to segregate, but simply to legalise an enormously profitable business of bawdy house keepers and panderers, who desire for their own profit to fix upon the people a diabolical trade in the souls and bodies of girls. Once established, with the vantage ground of legal protection, they will ply their trade as they have in the past, as they do to-day in Baltimore and other large cities, until from our whole land there goes up the stench of the moral corruption which engulfs all our youth, sparing no age and no condition in the social scale, so rapidly and so absolutely does injured purity avenge itself.

Segregation is inadmissible as a solution of the prostitution question because no legislative body may by any decree, or by however great a majority, give vice a legal status. It is true acts can be passed and force can be exerted to carry them out, but this does not make the enactment legal, and any right-minded judge can upset it as unconstitutional in the very first case coming to trial. We have too long lost sight of the fundamental fact that morality is the very foundation of the constitutions of all our States. In these instruments which constitute the bodies politic of our various States, the declaration is repeatedly made that it is a necessary part of the very life of a government to promote morality.

Florida says: "The liberty of conscience shall not be so constructed as to justify licentiousness, practices subversive of or inconsistent with, the peace or moral safety of the States or society." The Constitution of Arkansas declares: "Religion, morality and knowledge are essential to good government." The Constitution of the State of Maryland: "That no person shall be molested on account of his religious profession unless, under the colour of religion he shall disturb the good order, peace or safety of the State or shall infringe the laws of morality." Massachusetts affirms that: "Wisdom and knowledge, as well as virtue, diffused generally among the body of the people, are necessary for the preservation of their rights and liberties."

I quote also from The Commonwealth *vs.* Douglas, decided in the Court of Appeals: "When we consider that honest morality and religion and education are the main pillars of the State, and for the protection and promotion of which government was instituted among men, the preservation of the trust is essential to the happiness and welfare of the beneficiaries, which the trustees have no power to sell or give away. If it be conceded that the State can give, sell or barter any one of them, it follows that it can thus surrender its control of all, and convert the State into dens of bawdy houses, gambling shops and other places of vice and demoralisation, provided the grantees pay for the privileges." North Carolina, Virginia and West Virginia significantly add (mark well these words, quoted from the North Carolina Constitution), that "A frequent recurrence to fundamental principles is absolutely necessary to preserve the blessings of Liberty."

I wonder what prophet wrote that sentence! We are suffering to-day because we have forgotten some of our fundamental principles, without which no just government can long exist. All the great minds that have dealt with the great underlying principles of jurisprudence unite in agreeing with Bishop, one of our highest authorities, that the State rests upon three supports: "Morality, religion and education are the three main pillars of the State and the substance of all private good. A community from which they are banished represents more than the original chaos. Therefore they should be objects of primary regard by the law."

The rational and simple conclusion of the whole

matter then is this: We resolve that we ought, we can, we will fight this vice to its utter extermination in all our broad land; that instead of yearly sacrificing to impure lives thousands of our young men and women, the hope of our country, we will save them for a high and noble citizenship; that we will oppose segregation and regulation of vice in any and every form in which it may seek to establish itself on a legal or quasi-legal basis; and that we will instruct our own boys and girls, and all the youth of our land, in the simple, physiological facts necessary to guard them from physical and moral harm.

THE SUPPRESSION OF TUBERCULOSIS IN IRELAND.

By SAMUEL AGNEW, M.A., M.D.,

Medical Officer of Health for Lurgan.

THE time has now arrived when it becomes necessary to organise the different forces at our command so as to combat successfully the spread of tuberculosis. The ways and means have been very fully and clearly explained in the Interim Report of the Departmental Committee on Tuberculosis which has been recently published—a copy of which should be placed in the hands of every county councillor, every member of a sanitary authority, and every member of a local insurance committee in Ireland. The Local Government Board of England has already issued two circulars on the subject, accompanied by a memorandum on the administration of sanatorium benefit by the National Insurance Commission (England). The Local Government Board of Ireland does not seem to be anxious to do things in too great a hurry, which is rather to be deprecated, seeing that so many county councils are displaying an anxiety to get things into working order. Under the National Insurance Act, sanatorium benefit should now be available for insured persons, and insurance committees are aware that they are under a statutory obligation to provide proper treatment for all such as are attacked by the disease. This treatment may be given (a) in sanatoriums, hospitals, or other institutions, or (b) at tuberculosis dispensaries or other non-residential institutions, or in the patients' homes. The committees are not themselves empowered to provide institutions, their duty being to make arrangements with local authorities or suitable persons to the satisfaction of the Local Government Board. Having satisfied themselves that the cases are really tuberculous they are bound to make suitable arrangements with a view to proper treatment being provided in each case in appropriate institutions or in the patients' homes.

In Ireland the provision of sanatoria and the establishment of tuberculosis dispensaries are placed in the hands of the county councils, who are empowered to appoint county committees for the control and management of them; and to encourage these bodies to take up the work in a whole-hearted way, a very large subsidy is given to each county to assist in building suitable institutions, of which it is to be hoped they will avail themselves. The erection of sanatoria will, however, occupy some considerable time, and should not be undertaken without due consideration, and only after having had expert advice. There being no county medical officers of health in Ireland, such advice is not immediately obtainable, but in the establishment of a tuberculosis dispensary, they can place themselves in a position to secure it without any unnecessary delay. In providing such a dispensary the first essential is the appointment of a skilled tuberculosis officer with capacity for organisation,

who will be responsible for the general conduct and administration of the dispensary. The Departmental Committee recommend that such an officer should have at least £500 a year with prospects of increase, and I am pleased to observe that in my native County of Down, the County Council are advertising for such an officer, and have fixed the salary at £500 a year, with £150 for expenses. As the Departmental Committee have very carefully pointed out, and have strongly emphasized the point, a tuberculosis dispensary is not a building, but an organism. "The essential element which must always be present is the chief tuberculosis officer appointed by the local authority; standing in such relation to the medical officer of health and the general scheme of public health administration as may be defined by the regulations of the local authority; acting as expert adviser to the local authority and insurance committee in matters of diagnosis and treatment; controlling, supervising, or acting in consultation with, as circumstances may determine, the whole-time subordinate medical officers and private practitioners by whom treatment is given; and himself treating cases for which special skill and experience are required." A large proportion of the cases of pulmonary tuberculosis, and some cases of other forms of tuberculosis can be adequately treated in the patient's own home. Treatment provided by the dispensary will include not only general "sanatorium treatment," whether in a patient's home or in a shelter, but also more special methods of sanatorium treatment, for example, treatment by tuberculin. Under the provisions of the Insurance Act, the treatment of tuberculosis patients who are insured must be entirely separated from the Poor Law; and the establishment of tuberculosis dispensaries by the county councils will enable this to be done. By utilising the services of the medical officers of health, except in the case of county boroughs, where ideal dispensaries can be formed, a complete scheme of organisation can be worked out for each county, in which harmony and efficiency will be the leading characteristics. In the tuberculosis dispensary an item of great importance is the district nurse specially experienced in the treatment of tuberculosis patients. One of these should be placed in the district of each medical officer of health and under his direct supervision. A small cottage, such as a labourer's cottage, should be provided for her at a short distance from the doctor's dwelling, with sufficient ground attached to enable two or more portable shelters to be erected for the accommodation of patients who could not, for want of space or other reasons, be allowed to remain in their own homes; and in the larger centres the situation and surroundings of the nurse's cottage might be such as to afford space for the erection of six or eight shelters. Whilst under the direct supervision of the medical officer of health, the shelters and services of the nurse would be available for all patients, and private practitioners could treat their patients therein without any interference.

It is, of course, understood that the services of the chief tuberculosis officer or tuberculosis superintendent would be at the disposal of all the medical practitioners within the area; but as regards matters pertaining more directly to the public health and the prevention of the spread of the disease, he would be in closer touch with medical officers of health. These district shelters would simply be feeders for the sanatorium, which should, of course, be erected, and, I hope, will be erected

for each county, either separately or jointly, in which the most up-to-date treatment will be provided. Whilst the tuberculosis superintendent is a full-time officer, debarred from private practice, arrangements will have to be made with the medical officers of health and private practitioners for the treatment of all patients outside the sanatorium who do not undertake to pay for their own medical attendance. As far as those insured are concerned, they will have to be given free choice of doctor, and a panel formed of those doctors who are willing to act on the terms offered. This arrangement might be extended to all patients who are not in a financial position to pay for medical attendance. In the meantime it must be recollected that ordinary dispensary patients who are the victims of tuberculosis must be catered for by the insurance committees, if they are insured, and are not, therefore, in a position to demand poor-law relief. In conclusion, I would like to draw attention to something which must be done to facilitate the conduct of the campaign in Ireland. The restrictions which have been placed upon notifiable consumption by the Local Government Board under the powers vested in them by the Tuberculosis Act should be removed, or else tuberculosis should be scheduled amongst the list of infectious diseases after compliance with the terms of Section 7 of the Infectious Disease (Notification) Act, and this Act extended to all Ireland, as it has been extended to Great Britain. The medical officer of health must also be placed in his proper position with regard to the administration of the Dairies, Cowsheds and Milkshops Order, with adequate remuneration for his services. I would further suggest to the local medical committees that they should endeavour to frustrate any attempt to divert the treatment of tuberculosis patients from the care of the general body of the profession, so as to place them under the immediate control of a county specialist, assisted only by a staff of nurses. The domiciliary treatment of tuberculosis patients is as important as ever, and cannot be relegated to a peripatetic expert.

THE FORMATION OF A STATE MEDICAL SERVICE. (a)

By ROBERT R. RENTOUL, M.D., &c.;

Liverpool.

IN 1886 I obtained a translation of the German laws relating to National Insurance. I came to the conclusion that England must eventually adopt a similar scheme. Since then much "water" has run under the bridge, and now—after twenty-five years of lost time—we attempt to evolve a Service. Personally I feel it would give better national results if the Government made the employment of all doctors a branch of the Civil Service. Nationalisation of medicine is not so far off as some think. The State, or Municipalities, now appoint and pay doctors to look after the men in the Army, Navy, and Indian Army. The Local Government Board appoints Medical officers of health, Poor-law medical officers, and public vaccinators, the Prison Commissioners prison surgeons, and the Lunacy Commissioners see to the appointing—through the County Councils—of asylum doctors. The Board of Trade insists that certain ships shall carry surgeons for the treatment of crew and emigrants. The Colonial Office appoints Colonial surgeons, the Home Office factory surgeons, the Post Office

surgeons for their officials; while the Municipalities appoint doctors to fever hospitals and to inspect school children.

It is further suggested that they shall appoint doctors to treat sick school children; and now the Government has agreed to provide some 20,000,000 with State appointed and paid doctors. Some years ago I collected statistics to show that in 1901 about 7,565,385 persons in the United Kingdom obtained free medical treatment; not including some 6,000,000 quasi-charitable club members and 541,559 free vaccinators. If 14,000,000 more be added, you can see—or should see—that the proposal to put all Medical practice under State and Municipal control is not a mere dream; and, if we had a system of examination, pay, promotion, and pension, such as exists in the Army and Navy, then the condition of doctors would be greatly improved. I do not suggest that there would not be a fair number of non-State practitioners also.

As regards the chief points bearing upon a Public Medical Service, I suggest:—

First.—That the Insurance Committees receive from the Insurance Commissioners a sum of money equal to about 6s. per insured person per annum, this to be handed quarterly to the doctor of the insured person. Perhaps this 6s. might be increased to 7s. for each Post Office contributor, old age pensioner, and unemployed, as these will require more treatment.

Second.—That the Insurance Commissioners give 2s. 6d. per annum per member to the doctor or chemist who agrees to supply the insured person with medicines. This 2s. 6d. is rather small, if we wish to give reliable medicines to the sick public. You may have noticed that the average German allowance is 3s. 8½d. to the chemist. This 6s., plus 2s. 6d., would be the minimum sum asked for by the British Medical Association. Personally, I think 8s. 6d. is too small, even when extra fees are given for night, Sunday, and holiday work, and for operations. The German doctors at Leipzig have been granted 15s. per member per annum. I would here emphasise my regret that the Council of the British Medical Association did not send Commissioners abroad to study and report fully upon the Insurance Schemes of France, Germany, Austria and Denmark. The chemists were sufficiently practical to send their representative.

Third.—In order to meet Mr. Lloyd George's objection that he cannot or will not grant 11s. per member per annum, I would suggest that each insured person pay a yearly sum of 5s. (or about one penny weekly) to the doctor who treats him or her. In other words—that they pay the amount the better-class friendly societies now pay their doctors. These three sums of 6s., 2s. 6d., and 5s. would, with 14,000,000 insured persons, give doctors an annual income of £9,450,000, or £472 gross each—exclusive of confinements, vaccinations, notifications, operations, sanatoria, &c., these probably totalling from £50 to £100 each doctor yearly.

It is useless to contend that those making under £160 a year cannot pay this sum of about one penny per week. Sir R. Giffen, in 1886, estimated that the wages of the working classes had increased by 50 to 100 per cent. during the last fifty years, and that their total yearly income was £622,000,000. We all know that since 1886 their wages have, fortunately, increased, and will.

(a) Abstract of a paper read before the Medical Sociological Section of the British Medical Association, July 24th, 1912.

go on increasing. At the same time the prices of their foods have decreased by 15 to 20 per cent., rents having increased. There are other ways by which this 5s. a year could be easily provided. Thus it has been estimated that in England each year £23,000,000 is spent upon tobacco, £44,000,000 on sport, and £175,000,000 on the various kinds of concubinage. Take, again, the heavy expenditure upon funerals. In 1910, in England and Wales, 483,321 deaths were registered. It would be fair to estimate that these cost, in ground, mourning, and funeral, on an average £24,166,050. Half of this sum might be saved; and more would be saved if each municipality carried out funerals and burials. Why can't we spend £12,000,000 of this *on the living*, and not on dead bodies, and so establish a splendid system of supplying those under £160 a year with efficient medical, surgical, obstetric, and dental treatment, and medicines? It is idle for a Chancellor to tell us that he cannot raise sufficient money for this. Even if he taxed bachelors and sterile marriages, he could raise over £15,000,000 a year on a graduated taxation on their incomes. Take, again, the unnecessary expenditure upon alcohol—£162,797,229 during 1911; £5,192,571 more than in 1910. This amounts to £3 11s. 10½d. per head of the population, infant, adult, male and female—or £17 19s. 3½d. per family. What is the use of a Chancellor telling us that he cannot find the money. It is mere insult, mere bluff. If he wanted it for any other class of the community, he would readily find it! But the Chancellor has been taught by doctors, unfortunately, that doctors will not object to a little more medical charity from doctors. We, on the other hand, now maintain that *the utmost limit* of medical charity has been reached—nay, over-reached—and that a sponging public must cease sponging upon doctors. I have estimated that we doctors give as charity a sum equal to £8,678,000 yearly to the public in the form of medical charity; £4,000,000 of this to voluntary hospitals; £1,500,000 in private practice; £3,000,000 to clubs and tontines; £64,700 in free death certificates; and £114,250 in notifying births and not including bad debts. It is painful to read in Sir W. Plender's report that 171 doctors had to pay £1,458 to collectors in collecting part of the £113,980 income. Yet Mr. Lloyd George has the brazen effrontery to suggest that our present incomes should be further reduced yearly by £2,800,000. How do I prove this? Well, if we estimate that at present the average gross income of a doctor is £350 a year, this, with 20,000 doctors, amounts to £7,000,000; with 14,000,000 insured persons at 6s. this amounts to £4,200,000. He actually alleges we shall get it back out of the "maternity benefit" of 30s. During 1910, in England and Wales, 897,100 live births were registered, and this at 30s. each would give £1,345,000 yearly. But he knows that more than half these confinements are conducted only by midwives, and so this will be an additional loss of about £672,000 yearly to doctors. Would he agree to repeal the disease and death-dealing Midwives Act?

Fourth.—I propose that each person making under £160 a year subscribes to a Mutual Health Fund, out of which fees for night-work, Sunday and Bank Holiday work, operations, loans to the insured in arrears of payment, tickets to con-

valent homes, cost of rules, members' books, and salary of secretary should be met.

Fifth.—That each medical practitioner shall be appointed a public vaccinator and be paid the usual Government scale of fees—at present Boards of Guardians have now such power.

I claim that if we had such a Public Medical Service we would—(1) Relieve the voluntary hospitals of the well-to-do classes who now sponge upon these charities under the plausible untruth that they obtain better treatment there than elsewhere. (2) Supply all those making under £160 a year with efficient medical, surgical, obstetric and dental treatment and medicines; (3) Diminish the sick rate, loss of wages rate, permanently maimed, and the death rate. (4) Lessen the number of quacks, herbalists, bone-setters, midwives, prescribing chemists, clubs, tontines, sixpenny and shilling doctors, and quack medicine vendors. (5) Save doctors immense time in bookkeeping, in sending out accounts, bad debts, collectors, and County Court claims.

Such a service as this would give each of the 20,000 doctors about £522 yearly, in addition to their public and other appointments. And if we can put a stop to the gross abuse of voluntary hospitals, this would add at least £100 a year to each doctor's income. Let us recollect this, that unless we have the active co-operation of the doctors connected with voluntary hospitals a Public Medical Service will be a ghastly fiasco.

I am told by trades unionists that they have no objection to our receiving 15s. per annum per member. I look on the speeches of some friendly society men as mere put-up political clap-trap.

This is the broad basis of my proposal. There will be a lower income limit for country areas. We cannot give efficient treatment if we do not obtain a Government grant and help from insured persons. I think we should adopt a £160 income limit with a sliding scale of incomes at, say, £60, £80, £100, and £160, the yearly contribution by the insured person to vary with income. Also that if, in the future, a Public Medical Service be a financial success, we might adopt provisions for persons making up to £250 a year, upon a sliding scale of fees. We must watch that our maternity fee shall not be cut by midwives either employed by hospitals, maternity clubs, or acting for themselves. I am told they look upon the Insurance Act as a State endowment for Midwives.

I think all doctors acting under the State Insurance should be given all the benefits free, the payments being made by the State.

CLINICAL RECORDS.

A CASE OF MUMPS, FOLLOWED BY ORCHITIS OCCURRING IN A RETAINED TESTICLE.

UNDER THE CARE OF S. J. ROSS, M.D., CH.B.

Surgeon to Out-patients, Bedford County Hospital.

THE patient, a boy, æt. 14, contracted mumps. The attack was not a severe one, but on the eleventh day of the disease his temperature rose to 102°, and he complained of great pain in his right inguinal region. Upon examination, I discovered that the right half of the scrotum was empty; the right inguinal canal was also empty, but upon invaginating the scrotum and examining the canal, I caused excruciating pain which was referred to in the neighbourhood of Scarpa's triangle. Clearly the case

was one of orchitis occurring in an abnormally placed testicle. At the end of a fortnight the pain continued, with periods of marked exacerbation, so that I decided to remove the offending organ.

At the operation I found it placed just at the internal abdominal ring. I removed it and examined it microscopically. It was a very poorly-developed organ, and showed the typical signs of inflammation.

I record this case, which I am sure is by no means unique, for the following reasons:—

1. Orchitis accompanying mumps is a by no means rare complication, but is always of interest, as it is, as yet, an unexplained phenomenon. To talk of metastasis is to cover our ignorance by means of a term. Nevertheless, the condition clearly favours the organismal theory of the cause of the disease.

2. The "referred pain" is of interest.

3. There could be no doubt as to the correct treatment to adopt.

Misplaced testicles are nearly always undeveloped, atrophic, useless organs, as was the case in the organ we removed. They are liable to injury and inflammatory attacks.

Inflammation is the precancerous condition, and we have instances of sarcoma developing in a retained testicle. In this case the testicle was an ill-developed organ in an inflammatory condition, valueless functionally, a source of pain and even danger to the patient, and therefore he was better without it.

4. It is well to remember also that orchitis, following mumps, not infrequently ends in atrophy of the organ.

Of course, even an atrophied organ, if in its correct position, is better than an absent one, at any rate, in the eyes of the patient.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

TREATMENT OF STRICTURE OF THE URETHRA BY DILATATION—THREE CASES.—FIRST CASE.—The first case was that of a man, *æt.* about 50, who had been sent up to Mr. Boyce Barrow from the country. The stricture had lasted for many years, and the patient had been at various times in the hands of many practitioners. On admission, Mr. Barrow tried to pass a silver catheter, and discovered that a great many false passages existed. Especially were they shown when the finger being introduced into the rectum, it was found that the instrument was in a false passage, which was quite near to the bowel. The man himself had before stated that he was perfectly aware of the presence of the false passages, each of which he humorously said he was able to refer to under the name of some doctor. After a great deal of trouble Mr. Barrow was able to get a No. 2 into the bladder. No anæsthetic was used, as Mr. Barrow thought it a good thing to go very much by the patient's sensations in cases of false passages. He then tied in the catheter, for, as he remarked, if it were withdrawn there would again be the possibility of getting into the false passages when trying to pass it again; they would thus be irritated, and they required absolute rest to allow them to heal. The catheter was left in for two or three days, and when taken out a No. 5 was passed without any difficulty and tied in for three days. It was then removed, and a still larger one, No. 7, passed. There was slight difficulty this time, as a trial had been previously made, unsuccessfully, to pass it. Three days afterwards a No. 9 was passed, but not tied in, as metal bougies could be used now the natural passage was open, and the liability of getting into the false passages much lessened. After three weeks the patient left the hospital, although he had not

yet learned to pass a metal bougie upon himself, as Mr. Barrow considers so necessary in these cases.

SECOND CASE.—This was a case of absolute cure by metal bougies. The case showed pus in the urine, which, as Mr. Barrow pointed out, comes from the dilated urethra behind the stricture. He treated this patient, a man, *æt.* about 55, entirely by metal bougies, passing first a small one, No. 1 or 2, but as the urethra was in a septic condition it was not tied in; another instrument, No. 5, in two or three days to produce further dilatation; then every two or three days the urethra was further dilated up to 9 and 10, particular care being taken to treat the canal as gently as possible. Every time the stricture was dilated the passage of water was facilitated and the dilatation behind the stricture put into a better condition. Gradually the size of the instrument was increased up to 14, but the intervals were made longer, being augmented to one passage in a week. The patient was then taught to pass the instrument for himself, beginning by himself taking out the bougie passed by Mr. Barrow, and introducing it himself at once. On the next occasion he simply passed the instrument himself in front of Mr. Barrow. If the patient experiences any difficulty, the bougie is introduced by the surgeon until the patient acquires the necessary facility. Metal bougies are the best, Mr. Barrow considers, for the patient to use, as they can be easily cleaned by the patient himself and lubricated with an antiseptic when used, so the patient cannot do himself any harm. The patient is told to pass the instrument at first once a fortnight, and then once a month, and if he neglects this he is always liable to get a subsequent contraction of the passage. The necessity for passing the bougie by the patient becomes less frequent, but it should be done at least once a month. This second case, Mr. Barrow said, had undergone a preliminary treatment by urotropine and rest in bed for a week or two.

THIRD CASE.—The third case had been admitted to the hospital and put down on the list for the operation of perinæal section, owing to the presence of several fistulæ in the perinæum, through which the urine dribbled. Mr. Barrow, on seeing the patient's miserable general condition, decided not to operate at once, but put the man on urotropine and ordered rest in bed for about a week. The patient's condition being then better, he passed a No. 3 metal bougie. He said he would have passed a catheter, but the patient was in too bad a condition for it to be tied in. In a fortnight he had dilated the stricture up to No. 14, when the patient left the hospital with all his fistulæ, which had been very serious, closed up. The patient comes back to the hospital now and then, and the House Surgeon easily passes a metallic bougie.

Mr. Barrow said that strictures could be treated most satisfactorily by dilatation, but a certain amount of discrimination is required as to the method of dilatation. He emphasised his contention that when pus existed behind the stricture to be dilated it was not wise to tie in a catheter, and care should be exercised in passing instruments not to irritate the part of the urethra behind the stricture; in fact, it was not necessary to pass the instrument right into the bladder as long as the stricture was dilated. He laid great stress on the importance of teaching the patient to pass a metal bougie for himself after the stricture had been dilated by the Surgeon, so that the patient became master of the situation for the future, as he might not always be within touch of efficient surgical assistance. He thought that even when strictures had been divided by operation the patient very often gets recurring trouble if the urethra is not properly kept open, therefore it is well to also teach this class of patients to pass a metal instrument themselves.

THE Willesden Council has put forward a scheme for the approval of the Local Government Board for the building of a sanatorium and dispensaries in Willesden for the treatment of consumption.

SPECIAL REPORTS.

THE EIGHTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT LIVERPOOL, 1912.

FOURTH ARTICLE.

[FROM OUR SPECIAL REPRESENTATIVE.]

THE EXCURSIONS.

A LARGE percentage of those attending the meeting have availed themselves of the unrivalled hospitality of the medical profession and of prominent citizens of Liverpool. Garden parties, river trips, visits to works and dockyards, inspection of ocean leviathans, motor rides and theatrical performances for lady visitors provided a continuous round of entertainment, combined with gentle instruction to suit all tastes. In this respect there was nothing lacking, while the right royal way in which the civic authorities of Blackpool, Chester, Buxton, Southport, Llandudno and the Isle of Man received and entertained their guests will long be remembered by those who were fortunate enough to participate in one or more of these major excursions. It would be invidious to single out those individuals who spared no pains to make the visit of their guests as happy as possible, and exigencies of space prevent an enumeration of them all. Suffice it to say, therefore, that the Liverpool meeting will go down to posterity as one in which the hospitality shown was of the highest and most lavish description.

THE PATHOLOGICAL MUSEUM.

was housed in the Harrison-Hughes Engineering Laboratory of the University of Liverpool, a well-lighted building, which afforded every facility for the comprehensive display of the various exhibits. The material was grouped in fifteen sections, in charge of thirteen honorary sub-curators. The chairman of the Museum Committee was Professor F. T. Paul, and the Honorary Secretary was Professor Ernest Glynn. We may mention a few of the more important features in each section. (1) Tropical Medicine: The exhibit of the Liverpool School of Tropical Medicine, which was awarded a diploma of honour at the International Hygiene Exhibition at Dresden, 1911, was here on view. A series of specimens illustrating the various parasites infecting man was shown, and we noticed a collection of all the known species of tsetse-flies. Dr. Bayon showed some valuable specimens illustrating the bacteriology and pathology of leprosy. (2) Otology: A series of specimens and sections were on view here of the relations of the facial nerve, the semi-circular canals and other portions of the middle and internal ear, lent by Mr. Hugh E. Jones, of Liverpool. Mr. Malcolm Stockdale lent several specimens of aural and nasal interest. (3) Ophthalmological: The Liverpool Eye and Ear Infirmary was well represented in this section with the excellent series of specimens prepared and mounted by Dr. R. E. Harcourt. Another series, illustrating the comparative anatomy of the eye, was lent by Dr. W. T. Clegg, St. Paul's Eye Hospital. (4) Dermatology: The admirable series of photographs and drawings in this section were greatly admired, and were the subject of much comment. A large number were exhibited by Drs. G. Stopford-Taylor and R. W. Mackenna, who also showed their unique collection of wax casts of diseases of the skin, modelled from life at the Liverpool Skin Hospital. A series of coloured drawings, lent by Dr. David Walsh, to illustrate his paper on chronic and recurrent skin affections in heart disease, also attracted much attention. The President of the Section, Professor Walter Smith, and Dr. Louis Savatar, Manchester, also lent specimens and lantern slides. (5) Gynaecology and Obstetrics: A series of twenty-one specimens of sarcoma of the uterus was displayed from the museum of obstetrics and gynaecology: University of Liverpool. Other sarcomatous speci-

mens were lent by the University of Sheffield and also by private exhibitors. Miss Frances Ivens, Liverpool, showed several specimens illustrating tuberculous salpingo-oöphoritis. (6) Alimentary Section. A large number of oesophageal lesions were exhibited, many of them by Dr. Brown Kelly, Victoria Infirmary, Glasgow; while Dr. William Hill showed several instruments, mostly endoscopic, for dealing with diseases of the oesophagus. An interesting collection of concretions from the alimentary canal was lent by Dr. Owen T. Williams, Liverpool. Congenital deformities and specimens of malignant disease were much in evidence, having been contributed by many of the surgeons from Liverpool and Newcastle. Several stomachs were shown containing hair, wool and bits of matting, having been swallowed by lunatics and feeble-minded persons. (7) Cardiovascular Section: Several interesting specimens of gummata of the heart were exhibited, in some cases associated with the presence of aneurysm. New growths were illustrated by secondary sarcomata, some of them of a melanotic nature. Other specimens included tuberculous pericarditis, lent by Professor Lorrain Smith, University of Manchester, and a series of paintings of infective endocarditis, lent by Professor T. R. Glynn. (8) Genito-Urinary Section: Eighteen specimens illustrated the aetiology of hydronephrosis. Adrenal tumours were illustrated by numerous specimens lent by the Universities of Manchester, Leeds, Sheffield, Birmingham and Liverpool. Renal and bladder growths, as well as a variety of calculi, were all to be seen, and constituted a very fine display. Mr. R. A. Bickersteth, Liverpool, showed a series of X-ray prints illustrating the utility of (a) catheterisation of the ureters, (b) renal pyelography (the renal cavity being filled with collargol solution). (9) Section of Diseases of the Liver, Pancreas, Spleen and Lymphatic Glands: One of the most striking exhibits here was the collection of livers and kidneys, illustrating the neurotic changes found in cases of eclampsia, lent and described by Dr. J. H. Teacher, Glasgow. Some large actinomycotic abscesses of the liver were lent by the University of Liverpool. Specimens of lymphadenoma, tuberculosis, acute hæmorrhagic pancreatitis, among others, completed this interesting exhibit. (10) Section of Laryngology: This was contributed entirely by Dr. Logan Turner, of Edinburgh, and consisted of specimens illustrating sudden death from laryngeal obstruction, malignant and tubercular disease, syphilis, as well as tracheal and laryngeal diphtheria. (11) Section of Miscellaneous Specimens: In this section were to be found numerous examples of sarcomatosis, lent by Professor Beattie; other interesting tumours lent by the University of Liverpool; and a series of different types of sphygmomanometers, among other exhibits. (12) Section of Nervous Diseases: Professor Beattie and Dr. Arthur Hall showed some fine specimens from a case of diffuse neurofibromatosis in a girl, aged 17, in one of which could be seen the tumours growing on the cranial nerves. Several exhibits were shown illustrating tuberculous tumours of the brain, and there was one specimen of a pituitary tumour, together with the skull from a case of acromegaly, lent by the University of Liverpool. (13) Section of Radiography: This section was exceedingly well arranged and contained many exhibits of great interest. Stereoscopic transparencies were shown by Sir James Mackenzie-Davidson, Dr. G. F. Haenisch, Hamburg, and Dr. C. F. Bailey, Brighton. Radiographs illustrating the earliest stages of peri-bronchial phthisis were shown by Dr. Jordan, London. Dr. Knox, London, exhibited a series of microphotographs showing the cell changes in cases of cancer undergoing treatment with radium. Mr. C. Thurston Holland, Liverpool, showed some fine radiographs illustrating renal calculi under different conditions of apparatus, etc. (14) Respiratory Section: An instructive series of specimens here shown were those representing pulmonary thrombosis and embolism, particularly the three showing multiple embolic aneurysms of the pulmonary artery, following thrombosis of the veins of the leg, lent by Professor

Beattie and Dr. Arthur Hall, Sheffield. A rare specimen of tubercular pleurisy was lent by the University of Liverpool. Several morbid growths of the lung and pleura were also to be seen. (15) Section of Modern Anæsthetic Apparatus: Here were found collected together the very latest devices for administering the vapour of ether and chloroform with oxygen, either separately or in various proportions, lent by Dr. Thompson Kowling, Leeds; an apparatus for the nasal administration of nitrous oxide gas, lent by Dr. Francis W. Bailey; the apparatus for intravenous infusion anæsthesia, lent by Dr. G. H. A. Barton, London; and that for the intra-tracheal insufflation of ether, modified from that of Elsberg by Dr. R. E. Kelly, Liverpool, the exhibitor.

THE ANNUAL EXHIBITION,

though approached by somewhat dingy streets and housed in the now disused Gill Street Market, not far from the University buildings, was, by common consent, much better patronised than in some previous years. It was formally opened on the Tuesday by Sir James Barr. Those responsible for its organisation may well be congratulated upon the manner in which the various stalls were arranged, and especially upon the smartly-decorated appearance presented by the interior of the building as a whole. The general excellence of the exhibits was much appreciated by the visitors, and there was never really a dull moment on any of the four days during which the exhibition was open.

FOODS AND BEVERAGES.

Messrs. Armour and Co., Ltd., of London, were showing, in addition to their well-known nutritive products, "Vigoral," a highly concentrated beef essence, supplied in liquid or in cube form. They were also exhibiting a series of refined animal extracts, including desiccated powder, tablets, and elixir of thyroid gland. The preparations of G. Van Abbott and Sons, London, were of special interest to diabetics, and their biscuits and flour made of bran, gluten, or almond satisfied the most rigid demands of the dietician. George Back and Co., Ltd., London, were there with their well-known "G. B. Diabetes Whisky." Lemco and Oxo (Liebig's Extract of Meat Co., Ltd.) exhibited the penny pure beef tablets, known as "Bifti," which bring their famous meat extract within the reach of all. The same firm's "Fray Bentos Corned Beef" is a delicious product for the table; this and their ox tongues were also on show. The famous Peter's Milk Chocolate was much in evidence at the attractive stall of the Nestlé and Anglo-Swiss Condensed Milk Co., in addition to the firm's numerous brands of sweetened and unsweetened milk. Cerebos, Ltd., were offering a suitable pourer for their excellent table-salt to any medical practitioner not already in possession of one. The various preparations of Messrs. Brand and Co., Ltd., appeared most inviting, especially the beef broth, concentrated beef tea and series of invalid soups. The same firm was also showing their fever food, containing the tonic properties of meat essence, combined with egg proteids and cream, for use in tropical climates. Bovril, Ltd., was well to the front with a most attractive exhibit of their famous blend of meat extracts. Messrs. Fairchild Bros. and Foster were showing, in addition to "Panopepton," a food called "Laibose," containing the solids of whole milk and wheat. The complete food, beloved of infants, known as "Virol," was shown by that firm, and its valuable properties were convincingly demonstrated. At the stall of Messrs. A. Wulring and Co., the features of "Albulactin," the true milk-albumin, were displayed, and its uses in infant feeding conclusively shown. The same firm also exhibited their well-known Formamint Tablets. Mustard, patent barley, and groats were exhibited by Messrs. Keen, Robinson & Co., Ltd., The Horlick's Malted Milk Co., Slough, Bucks, were showing their inimitable preparation in the form of tablets, which have been found most acceptable by travellers, motorists, and others. The firm was also showing a novel form of feeder which possessed many advantages over those in common use. Manuel

Frères, of Lausanne (Switzerland), were showing their well-known Anti-Putrefactive foods, as used in the Lausanne régimes. Angier's Emulsion and Throat Tablets were exhibited by the Angier Chemical Co., Ltd. The Hygiama Foods Co. showed their specialities, Infantina and Hygiama, both favourite foods for infants. At the stall of Messrs. Savory and Moore, we noticed, in addition to their peptonised concentrated milk preparations, "Fructolax," a deliciously-flavoured hydrocarbon jelly laxative, and "Aphrodont" (Dental Foam), an elegant preparation for the teeth, agreeable to use, and having first-rate antiseptic properties. The Pascon Co., London, exhibited an entirely new soluble beef product, consisting of digested fibrin and albumin together, and containing no alkali. Biscuits, cocoa and wine, reinforced with Pascon, were on show. Cadbury's Chocolate and Bournville Cocoa represented the highest ideals in these two products and came in for well-deserved commendation. The Apollinaris Co. regaled visitors with samples of their excellent natural mineral table water, while Vittel Grande Source was to be tried at the stall of the Société Générale des Eaux Minérales de Vittel (Vosges). An attractive exhibit was that of the Buxton Spa, the water of which can now be bottled, being an absolutely pure English Table Water. Messrs. Ingram and Royle showed a number of excellent mineral waters, including those of Carlsbad, Contrexéville, Vichy. Hunyadi Janos, Giesshubler, and Friedrichshall. Some fine samples of cyder were to be tasted at the stall of Wm. Gaymer and Son, Ltd., of Attleborough, Norfolk.

(To be continued.)

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 10th, 1912.

HYSTERIC AND ORGANIC NERVOUS AFFECTIONS.

ONE of the principal signs which permit us, in a nervous affection, to affirm that it is organic and not hysteric is exaggeration of the reflexes, says Prof. Babinski.

Contrary to what was formerly believed, tendinous reflexes are not modified in hysteria; their exaggeration with eliptoid trepidation belongs exclusively to spasmodic paralysis of organic origin.

Hysteria does not produce weakening nor abolition of the tendinous reflexes; this phenomenon is only observed in monoplegia or hemiplegia of organic origin, associated sometimes, perhaps, with an hysterical condition. But the presence, it must be said, of exaggeration of the reflexes is not sufficient in itself to establish a diagnosis in certain cases. Other signs should be sought for, of which the principal are: reflex extension of the great toe, combined movement of flexion of the thigh and pelvis, the sign of pronation of the hand of the affected side.

The reflex extension of the toe, Babinski's sign, is characterised by extension and abduction of the toe on tickling the sole of the foot. This sign alone is sufficient to affirm the organic nature of the paralysis in a large number of cases. However, it is not always present. The sign of combined flexion of the thigh and pelvis may be observed in the following manner:—The patient is placed on a resisting plane, the head supported by a pillow, the body extended in the dorsal decubitus, the arms crossed on the chest. When told to make an effort to sit up, the thigh on the affected side is seen to bend and the heel to leave the ground. This sign is observed in a great number of cases of hemiplegia, and would seem to be due to the fact that such patients have less strength than normal individuals, and are not capable of maintaining the extension of the thigh on the pelvis.

The sign of pronation can only be observed while the hemiplegia is still flask. If the hand of the patient is placed in supination, on the healthy side, it keeps naturally this attitude and without difficulty, while on the affected side, immediately it is left to itself it returns to pronation.

EXTERNAL TREATMENT OF ŒDEMA.

Everyone knows by experience how tedious and unsatisfactory is the treatment of extensive œdema of the lower limbs by internal remedies. A simple treatment based on the physical phenomenon of osmosis has been tried with unvarying success by Dr. Pathault. It consists in wrapping around the limb a compress steeped in a strong solution of common salt (one ounce to the quart), and covering with absorbent cotton wool maintained with a bandage. This dressing is left on all night. The following morning one is astonished at the amount of liquid that has filtered through the wool; the sheets and mattresses are sometimes soaked. After a few days of the treatment the œdema has disappeared. The author affirms never to have met with failure, although he treated numbers of cases of œdema due to various causes—heart or kidney disease, phlebitis, and sclerosis.

The internal treatment should always be continued, or otherwise the œdema returns if the cause persists, but the external treatment, by relieving the tissues, facilitates considerably the action of the internal treatment and eases the efforts of the heart.

HYPERTRICHOSIS.

The slight down which sometimes ornaments (?) the upper lip of young ladies may be effectually treated by the following ointment, provided it is continued for a long time—a year at least. It is put on at night.

Acetate of thallium, 6 gr.
Oxide of zinc, 4 dr.
Lanoline, 1 dr.
Rose water, 1 dr.
Vaseline, 5 dr.

ERYSIPELAS.

Tincture of iodine, 1 oz.
Spirit, 1 oz.
Guaiacol, $\frac{1}{2}$ dr.

Paint on the inflamed surface; rapid cure.

GERMANY.

Berlin, Aug. 10th, 1912.

At the Gesellschaft der Charité Aerzte, Hr. His gave an account of investigations into the

SOFTENING OF GOUTY TOPHI.

However the subject of gout, he said, was attacked, there still arose fresh and fresh problems. They knew that under the name of tophus there were deposits of uric acid salts (principally urate of sodium), which in the shape of the finest needles crystallised out in the tissues, and there often formed compact lumps, sometimes of quite a large size. It was known that such a tophus, when once formed, did not with absolute certainty maintain its original size. It might become absorbed under inflammatory symptoms; it might grow gradually or by fits and starts; it might become less, and the diminution in size might take place under very remarkable colliquation. In the case of an officer aged 28 who had suffered from a severe attack of gout when young, large tophi formed in the mucous tissues of the back of the hand and in the region of the joints of the feet. In the course of treatment one of these tophi melted away. After it had been hard it liquefied, and with a Pravaz syringe one could draw out a fluid having a cloudy serous appearance. Within the fluid were a large number of leucocytes, which were completely loaded with debris of urate crystals, the leucocytes representing phagocytes. That was one of the possible courses towards recovery from tophi. The tophi of the subcuticular tissue were known; tophi of the ear almost always lay in the subcutaneous tissue, scarcely ever in the cartilage. But there were also cutaneous tumours. Lecorché had paid special atten-

tion to them. Showing some illustrations from Lecorché's work, he continued: They saw the skin covered with small vesicles. Whoever saw these for the first time would take them for pemphigus or pustules. They had a yellow look, and were surrounded by a red areola. If they were opened, a thick chalky like mass exuded, which consisted of innumerable needles of urates.

Such tophi might form very rapidly. During an attack of gout in one of the speaker's patients, in which several joints were affected, such a tophus formed in a night, and in the morning there was a tophus the size of a pea on the hand that completely fitted the description given by Lecorché.

We could reproduce several processes in these tophi artificially, when we injected uric or urates under the skin of rabbits or other animals. In this way we could follow the reactions beautifully.

When such a deposit was made the nuclei were at first destroyed; they appeared to be quite broken up and lost their normal structure. In a few days new cells forced their way in from the periphery; these were not destroyed, but remained with well-coloured nuclei. About the fourth day a process of phagocytosis began. The bodies of the cells were found to be filled with debris of urates. Some of the cells were small, and contained but one nucleus, others were multi-nuclear giant cells, which contained fragments of crystals.

Thus, not only chemical solution but phagocytosis played a part in the disappearance of tophi. If an examination of the parts immediately adjoining the deposit of urates was made, many cells would be found filled with debris of urates; farther away such cells were no longer to be seen. In spite of this, however, it could be proved that these cells wandered still farther. For example, if Indian ink was introduced into the deposit, the regionary lymph glands would be found to be filled with cells with inky contents. In these cases, however, crystals would be seen no more. The cells were in a position of being able to dissolve the crystals or to destroy them chemically.

In gout of the human subject, the masses of urates were covered in by an extraordinarily firm connective tissue, poor in cells, that passed through them and divided them into septa and dissolved them in individual groups. The immediate surrounding of the crystal deposit consisted of an infiltration wall containing cells in which pronounced giant cells similar to the giant cells of tuberculosis were present, with numerous nuclei arranged in order.

Benella was the first to show such needles of urates in the bodies of such cells. Amongst the contents of the rapidly formed skin tophi were glands consisting of numerous radially arranged urate needles, betwixt them a few red blood corpuscles that had come away through the puncture, and a small number of leucocytes. If the preparation were coloured it was seen that the nuclei, as in the animal experiment, were mostly broken and had lost their structure. Here also, as in the animal experiment, there was no phagocytosis the first day.

In that case, however, in which a tophus had existed for a longer time the phagocytosis could be recognised plainly; almost all the cells, which were all mono-nuclear, showed more or less remnants of crystals in their protoplasm.

It could be shown, therefore, that in the human subject, as in the animals experimented on, under certain circumstances the resorption of the tophi of urates took place by way of phagocytosis

HUNGARY.

Budapest, Aug. 10th, 1912.

X-RAY THERAPY IN TRACHOMA.

SOME two or three years ago Cassidy and Rayne reported favourable results in the treatment of trachoma and Roentgen rays. In Hungary Dr. Imre has experimented with the X-rays in seven cases, from which he draws the following conclusions: (1) The

effect of the X-ray therapy on the trachomatous process is beyond doubt, as evidenced by the decrease of the infiltration, the disappearance of the granules and the pannus, and a marked improvement of the subjective painful sensations. (2) It can be stated in a general way that the trachomatous granulations tend toward slow disappearance under the influence of radiotherapy; its influence on the infiltration is more marked; pannus is very favourably affected by the method of treatment. (3) Dr. Imre is unable to report a single case of complete cure of the trachoma, notwithstanding the great number of sittings, owing to frequent interruptions, the consistence of the tubes, which exert a certain effect on the power of the rays as emanating from the radiogenous tubes. (4) The tendency of the tissues to cicatrization was rather insignificant under this line of treatment. (5) As compared with other methods of treating trachoma (the expression of the granules, etc.), X-ray therapy is rather less effective in the form of trachoma unattended with deep infiltration (the so-called follicular conjunctivitis). (6) Dr. Imre failed to observe any harmful results from radiotherapy, either directly to the eye or in the form of any dermatitis. (7) Radiotherapy is entirely painless. (8) Those cases of trachoma which are not amenable to the ordinary method of treatment, or which proved unyielding to same, are beneficially influenced by the X-ray treatment, and should be subjected to it. Finsen's method is as yet *sub judice* in ophthalmological practice. As regards trachoma, some authors recommend ultra-violet rays as obtained from quartz lamps, but the results cannot as yet be given with any positiveness.

STOVAINE AS A LOCAL ANÆSTHETIC.

Dr. Nargyas reports some thirty various operative cases in which this anæsthetic was employed, including the opening of deep paraproctitis, the excision of a cancer of the lower lip, hydrocele, Bassini's operation for hernia, strumectomy, etc., the drug being used in one-half per cent., three-quarters per cent., and one per cent. solutions (in water), the total quantity used 0.12. He summarises the results as follows:—(1) Complete anæsthesia was obtained in all thirty cases. (2) There were no symptoms of poisoning in any of the cases, as evidenced by the pulse, respiration, reaction of the pupils, and the central nervous system. (3) The anæsthesia ensues almost at once, so that the operation can begin immediately after the injection. (4) The effect lasts about twenty minutes, and it is distinctly circumscribed, never extending beyond the infiltrated tissues. (5) The wounds do not bleed any more than at other operations, although stovaine is counted among the vaso-dilators. (6) Contrary to cocaine, no hyperæsthesia was ever observed after the effect of the drug had ceased. (7) The weaker solutions are as effective as the one-per cent. solution.

THE FREQUENCY AND DIAGNOSIS OF APPENDICITIS DURING THE PUERPERIUM.

At the last meeting of the Interhospital Medical Association, Dr. Zombor read a paper on the above subject. He said that the frequency of appendicitis during pregnancy is not greater than out of it. Perhaps, indeed, it is less frequent, because in women the appendix is not infrequently affected by extension of inflammation from the adnexa, and such infected women are likely to be sterile. It is rather easy to make mistakes with regard to the existence of the affection. In one case, recently seen, a patient was supposed to be suffering from typhoid fever, but there was immediate improvement after the incision of a large abscess. It is difficult to map out the induration of appendicitis in pregnant women, but if the patient is put on the left side in order to allow the uterus to drop out of the way, this can usually be accomplished. Acute septic conditions in the puerperium often come from the appendix. Sub-acute infections come from the ovaries. It is not always easy to differentiate ectopic pregnancy from appendicitis, and sometimes it will be found that the appendix is adherent to an ectopic gestation sac. Intra-pelvic appendicitis is

extremely difficult to differentiate from other pelvic affections, and at times may be mistaken for intra-pelvic phlebitis, or may give rise to suspicion of some infectious thrombosis of the intra-pelvic veins. In these cases, however, unless there is confirmation of the suspicion by the occurrence of phlegmasia in the leg, it is easy to suspect appendicitis and treat for that condition. Undoubtedly the statistics of appendicitis in pregnancy, as so far given, have been too unfavourable. It has been said that most of the mothers perished and very few of the children lived. As a matter of fact, however, if the case is taken in time, the great majority of the mothers will be saved and the pregnancy will continue to term. On the other hand, another important reason for not delaying the operation in these cases is that at times a dead foetus has been found, and with the colon bacilli present in the cord, and evidently the cause of the death as the result of communication of the infection from an untreated appendicitis. Marks had suggested (said Zombor) that in the later months of pregnancy premature labour should be induced and then the appendicitis treated. Pinard's advice is better, however. He says, treat appendicitis without any attention to the woman's condition, and it will usually be found that the pregnancy will go on to term. The advisability of operating even for mild symptoms that occur early in pregnancy has been suggested in order to avoid the dangers of the subsequent course of the case. Unless there have been well-marked symptoms, however, the appendicitis may only have been catarrhal and not necessarily suppurative.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

THE INSURANCE ACT.—A joint meeting of the Belfast Division of the British Medical Association and of the Belfast Medical Guild was held in the Medical Institute on Thursday evening, August 8th, to which every registered medical practitioner in the city was invited. The agenda included the consideration of a guarantee fund and a discussion on a Public Medical Service, but little time was found for these, as most of the evening was taken up with a report on the doings of the Representative Meeting of the British Medical Association, and a discussion on matters connected with sanatorium benefits. No resolutions were submitted, but the meeting accomplished the purpose for which it was summoned—to keep the members in touch with all that is being done in connection with the Act.

LONDONDERRY COUNTY COUNCIL AND SANATORIUM BENEFITS.—At a meeting of this Council, held on August 9th, a long discussion took place on the appointment of a Tuberculosis Officer. It was proposed to appoint an officer temporarily from next January, at a salary of £350, with £50 travelling expenses. Mr. McCarthy, the Local Government Board Inspector, expressed a doubt about the Council obtaining the services of a good man at the figure named, and said that some of the other counties were offering a little more. After some discussion it was decided to postpone making the appointment till October, and meantime to advertise it.

BELFAST DISTRICT LUNATIC ASYLUM.—The annual report of the Medical Superintendent, Dr. William Graham, has just appeared, embracing the medical statistics for 1911 and the financial accounts for the year ending March 31st last. The admissions were 17 per cent. less than the previous year, and included 99 males and 134 females, 233 in all. The total number under treatment was 1,474. The discharges were 130, of whom 87 were recoveries, a ratio of recoveries to admissions of 37.3 per cent., and to the number under treatment during the year 5.9 per cent. The net cost of each patient chargeable to the city is £11 18s. 6d. The villa colony system, of which Dr. Graham is so enthusiastic an advocate, seems to be working very well, but a sum of about £88,000 will still be necessary before it can be completed and all patients transferred

from the old town asylum to the villa colony at Purdysburn. The Inspector of Lunatics, Dr. W. R. Dawson, strongly supports Dr. Graham's plea for the hastening on of the new buildings and the completion of the new system.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE SOURCE AND DATE OF THE ORIGIN OF SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The recent discussion of the *early history* and present knowledge of SYPHILIS very appropriately contributed to the inauguration of the new domicile of the Royal Society of Medicine. And the perusal of the report of the same has once more brought impressively home to me the existence of the too obviously chronic—indeed, apparently, in some degree incurable—defect of our present theory and practice: that which owes its corroding influence to the negative opportunities afforded by the *non-existence* of a continuous chain of medical tradition and of an associated authoritative (selecting, filtering) and transmitting body (of the most enthusiastically devoted and most highly accomplished of living professional experts), in every succeeding generation. Slight, indeed, is the prospect of the attainment of such consummation within the boundaries—and by the methods—of the British Empire, as we know it! I do not here propose to examine the significance of the allusions of the "Father of Medicine" or of his great apostle of Pergamum, convincing as they are to me personally. I shall begin with a witness of the *Middle* (known to presumptuous ignorance as the "DARK") Ages.

GULIELMUS DE SALICETO, "insignis medicus et chirurgus," flourished at Verona in the middle of the "thirteenth, the greatest of centuries"; and died in the year of grace 1280. His treatise on surgery—necessarily in MS.—was epoch-making, and was one of the earliest of its class to engage the active attentions of the representatives of the novel art of printing: *Incipit Cyruurgia Magistri Guilielmi de Saliceto Placentini.—Explicit opus Guilielmi de Saliceto in Cyruurgia Placentiæ impressum ad exemplar originalis ipsius Magistri Guilielmi. Anno ab incarnatione domini M.CCCCLXXVI. die XV. Maii.*

(And here it is interesting to recall the fact that FRACASTORIO, the author of the poem *Syphilis*, and the inventor of the name, was also a Verona physician.)

The subjoined sectional paragraph will, I believe, prove as interesting to all inquiring readers, as its contents must surely prove convincing to all reasonable ones:

"DE PUSTULIS ALBIS ET SCISSURIS ET CORRUPTIONIBUS, QUÆ FIUNT IN VIRGA ET CIRCA PRÆPUTIUM PROPTER COITUM CUM MERETRICE VEL FÆDO AB ALIA CAUSA.

"Hæc ægritudo semper accidit ex frigido vel materia ventosa retenta inter præputium et pellem virgæ, et quia non expirat, crescit et multiplicatur in loco. Vnde cum neglecta fuerit in principio—iterum aliquando multiplicatur, quia corrumpitur pellex et denigratur, et corroditur cum hac substantia virgæ, quæ amplius restaurationem non recipit. Et accidit cum hac corruptione febris et fluxus sanguinis, et mors multoties. Cura festinanda est—mundificetur—inuoluatur—donec corruptio remota fuerit. Si vero non remoueri possit, et in tantum augmentata sit, quod denigraverit locum, tunc signum est mortificationis. Tunc intendas remotionem denigrati corrupti radicitus, si est possibile, cum ferro ignito separando corruptum a sano, quia si hoc subito non ferret, non cessaret corruptio augmentari, donec totum membrum corruptum foret.—Attende hic, quod ablutio cum aqua frigida et abstersio cum petia munda, et iterum ablutio, dum incipit post coitum cum fæda muliere aliquod corrup-

tionis futuræ vestigium, defendit perfecte virgam a corruptione futura, saltem ob illam causam, maxime si post illam ablutioem fiat roratio et quædam ablutio, vel loci iam ablutii aspersio cum aceto medico aut petiis in aceto infusis virga totaliter inuoluatur. Pulvis hermodactylorum valde utilis est *porris virgæ* et aliis corruptionibus."—If the above quotation does not represent an easily recognisable, and thoroughly reliable, description of the clinical entity which became known to remote posterity as *Syphilitic PHAGÆDENA* we must, I fear, begin to lose all faith in the reliability of written testimony!

There are many—very many, indeed—other witnesses to similar clinical facts, in the annals of each of the civilisations of which any medical record has been preserved. So we need not wait to discuss the case of the patriarchal infection of the house of Pharaoh ("because of Sarai, Abram's wife"), or that of Job (although accepted as genuine by the highest expert authority of the CHURCH), or that of David ("Oh, Lord! heal me, for my bones are vexed.")

But the courtly John of Gaddesden—who secured special celebrity and success by adopting at the English Court the scarlet treatment of *small-pox* which had been employed in "far Cathay" since time immemorial—also gives in his famous *Rosa Anglica* (circa 1305 A.D.) highly suggestive sanitary counsel; quite skillfully formulated so as to anticipate sexual infection, and neutralise the consequences of its occurrence: "*Sed si quis vult membrum ab omni corruptione seruare, cum recedit a muliere, quam habet suspectam de immunditie, lauet illud cum aqua frigida cum aceto mixta, vel de vrina propria interioris vel exterioris intra præputium.*—In illo vino madefiat pannus lineus vetus, et superponatur loco ægro: *Vulnus enim desiccat, et cancrum interficit et ulcerat.*" I must, of course, leave to the "private judgment" of the reader whether the suggestions embodied in the above sentences were likely to have been inspired by the consciousness of a pervading necessity for prophylactic defence of the delicate pseudo-membranous surfaces against the contact infection of gonorrhæal balano-posthitis. And a further spring, upwards in latitude and downwards in time, brings us to a proclamation of the Caledonian monarch, James IV.: "It is our Souverane Lords will and the Commend of the Lordis of his Counsale, send to the Provost and Baillies within this burt, that his Proclamation follow and be put till execution, for the escheving of the greit appearand danger of the infection of his Leiges fra this contagious sickness, callit the Grandgor, and the greit uther Skayth, that may occur to his Leiges and Inhabitans within this burt, that is to say, we charge straitly and commands be the Authority above writtin, that all manner of personis, being within the freedom of this burt, *quilks are infectit or hes been infectit uncurrit with this said contagious plage, callit the Grandgor*, devoyd, red and pass furt of this Town and compeir apou the sandis af Leith, at three hours before none; and thair sall thai have and fynd Botis reddie in the havin ordanit to them be the Officeris of this burt, reddely furneist with victuals, to have thame tho the Inche, and thair to remane quhill God proviyd for their Health. And that all uther personis, the quilks taks upon thame to hale the said contagious infirmity and taks the cure thairof, that they devoyd and pass with thame sua that nane of thair personis, quihilks taks sic cure upon thame, use the samyn cure within this burt in pus nor peirt any manner of way. And wha sa beis, foundin infectit and not passand to the Inche, as said is be *Monday* at the Sone ganging to, and in lykways the said personis, that takis the said Cure of Sanitie upon thame gif they will use the samyn thai and ilk ane of thame, salle be brynt on the cheik with the marking Irne, that thai may be kennit in tym to cum and thairafter gif any of tam remanis, that thai sall be banist but favors."

The preparation and promulgation of the above document were hardly attributable to fear of the contagion of blennorrhagia, or to any instinctive loathing of the national "YOUK"; which then

formed as distinctive an item of the Caledonian outfit as the *tartan* or the *bagpipe*. But it bears date, indeed, of the year 1497; which, as the advocates of the Columbian source of the original *lues venerea* may suggest, is quite compatible with their own view. (The date is, of course, reminiscent of the Borgian gifts of the first "first meridian" to the world, in general; and the University of Aberdeen to Scotland, in particular.)

The discussion was, very appropriately, opened by Dr. Norman Moore; who is well known throughout the whole professional world as one of its most gifted and accomplished citizens—celebrated as highly for his general scientific and literary and historic attainments as for his rare professional skill and acumen. I was somewhat surprised, accordingly, to find his opinion on this question ranging with that of the orthodox "general"; and must close with the expression of some faint hope that he may still see his way to modify the same.

I am, Sir, yours truly,
JOHN KNOTT.

2, Sallymount Terrace, Ranelagh, Dublin.
July 25th, 1912

THE NECESSITY FOR A NECROPSY IN EVERY CASE OF DEATH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In his usual terse and graphic style, Dr. J. C. McWalter, in the paper appearing in your current issue, deals with the above subject. From the point of view of the sciences of medicine and statistics, the Registrar-General's records in these islands are grossly incorrect and misleading. For a long time my attention has been directed in this matter to the certification of infantile death. If the returns are looked through, I doubt whether one per cent. are put down to one of the most frequent causes of death, namely, improper feeding. Many of these cases ought to have also ascribed as a powerful contributory cause, the use of baby-quieting quack medicines. It still remains the fact, in spite of recent successful attempts in some localities to disseminate knowledge among poor mothers, that infants in vast numbers are fed, instead of upon milk, upon all kinds of foods with which their digestive organs are no more able to act than they could upon so much bran or sawdust. The baby is in frequent pain, and is as often dosed with soothing syrup which, although now rarely containing morphia, is made up of some cheap carminative with enough alcohol to relieve temporarily the colic. The end is very often death from convulsions or diarrhoea. In nine cases out of ten the certificate gives one of these maladies as the cause of death, if it do not set it down to "teething." Teething is a physiological process, never pathological, and to ascribe a death to this process of development is about as scientific as to set it down to a visitation of God. I enclose my card, and beg to subscribe myself

Yours truly,
STATISTICIAN.

Birmingham, August 9th.

"IN VAIN IS THE NET, ETC."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Lloyd George's latest attempt to placate or cajole the profession is made through the medium of the *Nation*, not a very happy choice, seeing that this paper—as you have been obliged on several occasions to point out—has too frequently distinguished itself by depreciation of medical science and gratuitous disparagement of medical practitioners. A recent number, however, contains an article by Mr. Lloyd George on the Insurance Act. After reference to the fact that the Commissioners had invited over 30 medical men on to the Advisory Committee, and that they had held "useful and amicable" conferences, Mr. Lloyd George expresses his confidence that when the new regulations are published they will be found to contain provisions which will remove some of the

most anxious fears of practitioners as to the conditions under which practice will be carried on under the Act. He thinks that the profession will find that they are amply safeguarded against the danger of being subjected to a kind of disciplinary jurisdiction, exercised by a body of laymen, in matters which are peculiar to their own profession. He goes on to declare that it is the desire of the Government to pay the medical profession fairly. He holds that the Plender report proves that the financial basis upon which remuneration was computed was not as wide of the mark as some violent critics have affirmed, but if a case is made out for a further financial provision the Government are prepared to recommend the House of Commons to increase the grant. Sir William Plender's report will, he thinks, be of great assistance in the completion of the task, and they are willing and anxious to receive any information which will further assist them in arriving at a just conclusion. When the report of the Committee reaches the Commissioners they will be in a position definitely to advise the Government as to what addition (if any) it will be reasonable to make for the remuneration of the profession. It is difficult to guess what object Mr. Lloyd George considers likely to be gained by this pronouncement. It will no doubt serve as a much-needed advertisement for the *Nation*, but it will hardly have more weight with the men to whom it is addressed than the similar empty verbiage with which they have already been regaled literally *ad nauseam*.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

August 6th.

OBITUARY.

DR. T. L. ROGERS, OF ELTHAM.

WE regret to announce the death of Dr. Thomas Lawes Rogers, which took place at Eastbank, Eltham, on August 7th, at the age of 83. The deceased was the third son of the late Mr. Joseph Walter Goddard Rogers, of Alvediston, Wilts. He qualified as M.R.C.S. and L.M. in 1853, M.D. St. And. in 1857, becoming M.R.C.P. in 1860. In 1854 he joined the first battalion of the Coldstream Guards. With this regiment he went through the Crimean War, and was granted a medal and clasp for that campaign. He retired from the Army in 1858 and became Medical Superintendent of the Rainhill County Lunatic Asylum, Lancashire, where, before his service with the Army, he had temporarily acted as Assistant Medical Superintendent for a year. Dr. Rogers retired in 1888 and devoted the remainder of his life to voluntary work on various committees, such as the Charity Organisation Society, the Workshop for the Blind of Kent, and many others, in which he was associated with his lifelong friend, the late Mr. Brooke Lambert.

In 1893 he was elected a member of the Managing Committee of the Dreadnought Seamen's Hospital at Greenwich, where he took not only a great interest in converting an old and unsuitable building into a properly equipped hospital, but he was also one of the promoters in the work of organising the new School of Tropical Medicine at the London Docks.

He was elected Vice-President of the Seamen's Hospital Society in 1909. He married in 1863 Henrietta, the eldest daughter of the late Admiral C. H. Binstead, Deputy-Lieut. for the County of Yorkshire, and leaves one son and five daughters.

MR. J. S. SEQUEIRA.

WE regret to announce the death of Mr. James Scott Sequeira, M.R.C.S., L.S.A., of Crescent House, South Hackney, which took place on the 9th inst., at a nursing home, a few hours after an operation. The deceased, who was 84 years of age, was the son of Mr. James Sequeira, of Aldgate and Bow Road, E., surgeon—a profession which has claimed the services of six members of the family. His great-grandfather,

Isaac Henrique Sequeira, M.D., a native of Lisbon, was the first of the family to settle in London. As a physician he was a notable man, and died at Mark Lane in 1816, when he was the oldest Licentiate of the Royal College of Physicians. The family in Portugal had long practised as physicians, Dr. Henrique's grandfather and two uncles having all been of that profession. As a consequence Mr. Sequeira brought unusual experience and ability to aid him in his profession. Born in High Street, Whitechapel, he practised under his father at Jewry Street, Aldgate, and then at Leman Street. In 1852 he went to Australia and returned in 1857, and in 1860 he served an appointment at Limehouse. For 21 years he was Treasurer of the East London Industrial School and Medical Officer, and for 47 years manager at St. Mark's, Whitechapel. He was also Manager under the London School Board at Old Castle Street Schools and at Gainsborough Road Schools, and for 34 years Medical Officer to the Whitechapel Union. Mr. Sequeira was a Member of the North-East London Clinical Society and a Member of the Council and Trustee of the City of London Entomological Society.

Mr. Sequeira retired from active practice about 15 years ago, and his wife died shortly after. He leaves an invalid daughter and three sons, of whom the eldest follows the family profession, the second is a clergyman, and the youngest a Surgeon in the Navy. Mr. Sequeira had been blind for some years.

REVIEWS OF BOOKS.

EDUCATION. (a)

THE question of education is one of the most important of our highly progressive, or, at least, continuously restless, twentieth century. Its problems have to be considered by every reasoning member of every one of our civilised communities; by female and male, by the private voter as well as by the public official. The doctrine of formal discipline, as the author of this suggestive volume impressively indicates, was implied in the educational practices of the Greeks and the Romans, dominated the ideals and methods of scholastic education, and culminated in the barren formalism and logical subtleties of university disputations. But the doctrine was first clearly formulated as an education theory in the seventeenth century, especially by Locke. As any clear-minded observer would have anticipated, the progressive modification of enviring circumstances and conditions tended to modify and alter, *pari passu*, the special requirements of education. The modern view came to regard the *process* of learning as the one thing needful, and not the items of mental furniture introduced by its efforts. This view, which came to flourish in the eighteenth century, was something of a reactionary movement towards that of mediæval scholasticism; and the succeeding swing of the pendulum in the opposite direction was the vigorous repudiation of the pedagogic Herbart in the first quarter of the nineteenth century. In his system, which has experienced both wide diffusion and strong support, the important question is: what experience can the child be made to assimilate? "Mental power is a function of the organised experience of the individual." In the preceding generations, discipline of the *memory* took precedence of all other mental exercises; and its most efficient training was afforded by "the mastery of material which had no inherent interest for the child." Of course, a reactionary wave of formal discipline again swept over civilisation. The conflict between the claims of the classics and mathematics, on one side, and the natural and social sciences, on the other, came to distinguish the third quarter of the nineteenth century; and to furnish ample employment for the minds and pens of leading doctrinaires. Huxley and Herbert Spencer were the most vigorous protagonists for the

claims of the sciences. Both were far more lightly equipped than the average members of their respective audiences seemed ever to conceive; the former, although an expert in "natural" science, knew nothing of the Aristotelian philosophy and scholastic theology which he presumed to depreciate and professed to be able to overturn.

In this well written and "practically" philosophic volume Professor Heck gives the reader a very admirable summary of the most important views that have been held and defended by the most important authorities of recent times. The subject is so vast that it is, of course, quite impossible to discuss the varied opinions—and modes of practice thereon founded—within the limits of a review. Accordingly, we conclude by recommending the reader to learn and mark, as well as inwardly digest, the contents of this volume. We confidently guarantee the wholesome quality, as well as taste and flavour, of the contents.

MEDICAL NEWS IN BRIEF.

The Treatment of Tuberculosis in Ireland.

AT a recent meeting of the Joint Committee of the Irish medical profession held in Dublin, the following resolution was passed:—

"That in consonance with the action taken by the British Medical Association the medical members of the Irish Advisory Committee be called upon to resign."

The Committee also resolved "That all practitioners be called upon to refrain from accepting any post or office in connection with the administration of sanatorium benefit until the lines on which such benefit is to be administered shall be approved by the Committee." Another resolution appealed to the Local Government Board not to sanction the appointment of any chief tuberculosis officer who has not had such experience and was not of such standing as would command the confidence and enlist the co-operation of the practitioners with whom he would have to work; and a fourth resolution, while appreciating the great work already done by the Women's National Health Association, expressed its strong disapproval of the action of that body "in attempting to usurp the functions and powers of the statutory local authorities in regard to the establishment of sanatoria and tuberculosis dispensaries under the Insurance Act and the Tuberculosis Prevention Act."

The Committee further adopted certain principles as essential to the efficient working of the tuberculosis dispensaries. The chief of these are that the chief tuberculosis officer should be a whole-time officer at an annual salary of not less than £400, excluding travelling expenses, and that his duties should be confined to organisation and to consultation with the medical practitioners in charge of the patients; and that the treatment of the patients should be carried out by their usual medical attendant at a scale of fees for each visit to be arranged locally with the administrative authority by the local medical committee.

Annual Meeting of the British Dental Association.

THE thirty-second annual general meeting of the British Dental Association opened in Glasgow last week. Twenty-five years have elapsed since the association have met in annual conference in the city, and a cordial welcome was extended to the representatives, numbering fully 350, who took part in the proceedings. The meetings were held in the University, where the members were received by Professor T. H. Bryce, Regius Professor of Anatomy, in the absence of Principal Sir Donald MacAlister. The gathering which took place in the Bute Hall was largely attended. After an address by Professor Bryce, Mr. W. B. Paterson, the retiring president, delivered his valedictory address, and was presented with a presidential badge by Mr. J. H. Badcock. Mr. Rees Price was then inducted to the office of president, and delivered his inaugural address. Mr. W. A. Rhodes,

(a) "Mental Discipline and Educational Value." By W. H. Heck, M.A., Professor of Education, University of Virginia. Pp. 308. London: John Lane, 1912.

Cambridge, was elected president-elect of the association. In the evening the members attended a reception in the City Chambers given by the Lord Provost and Corporation.

The Royal Maternity Charity of London.

An appeal on behalf of the Royal Maternity Charity of London, 31 Finsbury Square, E.C., has recently been issued, signed by Princess Christian, President; Evelyn Lady Stanhope, Lady Iddesleigh, Lord Avebury, Treasurer; Mr. R. Inigo Tasker, Chairman; Mr. John Whittington, Vice-Chairman; and Drs. Septimus Sunderland and Henry Russell Andrews, Physicians.

It is stated that for 155 years the Royal Maternity Charity of London has been helping the very poorest married women whose position, but for timely assistance, would be helpless and hopeless. At the most momentous time in a woman's life the Charity sends its nurses and doctors, and supplies medical comforts to alleviate the suffering of those who have to face the ordeal in a state of destitution. When it is seen that the subscriptions only amounted to £365 10s., with the meagre sum of £92 in donations, during the past year, and that 2,102 cases were attended, it will at once be manifest how hopeless the position of the Charity must soon become without the help of a large number of new subscribers and donations specifically given towards the liquidation of the debt. Few expenses are incurred in the management of the Charity, as compared with lying-in hospitals, beyond the payment of a secretary and small fees to the doctors and nurses, and contract charges for medicines. The institution has helped over 564,000 poor married women since its inception.

A Special Tuberculosis Exhibition.

An exhibition of appliances, fittings, materials, and products relating to sanatoria, tuberculosis dispensaries, and the treatment of tuberculosis will be opened on August 26th at the Offices of the Society of Medical Officers of Health, 1 Upper Montague Street, Russell Square, London, W.C.

A special section will be devoted to the heating and lighting of sanatoria, dispensaries, and institutions generally, and numerous exhibits will deal with the preventive and curative aspects of the problem of tuberculosis in the United Kingdom. It is intended to keep the exhibition open for twelve months, the exhibits being varied and added to as improvements occur.

The Hospital Sunday Fund.

At the last meeting of the Council of the Metropolitan Hospital Sunday Fund, held at the Mansion House, the Lord Mayor, Sir T. Boor Crosby, M.D., presiding, it was reported that the total of the fund to August 2nd amounted to £52,300, which added to the £5,661 distributed last December, brought the total for the year up to £57,961. This year 257 institutions had applied for grants from the fund, being two less than in 1911, and the Committee now recommended the distribution of £52,294 to the several hospitals, institutions, dispensaries, and nursing associations, as shown in the appendix. The Committee had been informed that it was the intention of the Brixton Dispensary to participate in the proceeds of Sunday cinematograph shows, but to the best of their information nothing had yet been received from this source by the dispensary. The Committee, while recommending an award this year, were of opinion that the governing body of the dispensary should be informed that no grant could be made in future if their intention was carried into effect. Seven and a-half per cent. of the total sum available for distribution was appropriated to the purchase of surgical appliances during the ensuing year, and 2½ per cent. for district nursing associations.

The following resolution was then passed:—"The Committee of Distribution, having been informed that the sum allowed by them as the average cost for out-patient attendance has given rise to some dissatisfaction, recommend that the question be again investigated before next year's distribution. The Council

therefore request the Distribution Committee to make such investigation, and for this purpose empower them:—(1) To add to their number any gentlemen whose advice and assistance may be desirable; (2) to incur any reasonable expense in the examination of the accounts of the out-patient departments of the hospitals."

The various awards recommended by the Committee of Distribution and approved by the Council for 1912 were then read.

The Oxford Ophthalmological Congress.

As the outcome of a discussion upon miner's nystagmus (neurosis), which was held on July 19th last, at a meeting of the Oxford Ophthalmological Congress, the following resolution was unanimously passed:—"That, in the opinion of the Congress, the character of the illumination is the chief factor in the production of miner's nystagmus, and that a Departmental Committee should be appointed to make inquiries into and report upon the exact conditions under which the disease occurs."

The Middlesex Hospital Medical School.

The following scholarships, medals, prizes and certificates have been awarded to the successful students for the winter and summer sessions of 1911-12:—

Scholarships.—Second Year's Exhibition, S. W. M. Jones; Hetley Clinical Prize, T. L. Hardy and C. Helm, prox. acc.; Freeman Scholarship, L. C. Rivett; Lyell Medal and Scholarship, T. L. Hardy; First Broderip Scholarship, T. L. Hardy; Second Broderip Scholarship, E. A. Wilson and H. J. S. Shields, equal.

Prizes.—Inorganic Chemistry, D. A. R. Aufranc; Organic Chemistry, D. W. J. Andrews and W. H. Lloyd, equal; Physics, D. A. R. Aufranc; Biology, H. W. Lewis; Practical Pharmacy, A. B. Hacking; Histology, W. T. Warwick; Embryology, L. G. Phillips; Physiology, L. G. Phillips; Practical Anatomy, S. W. M. Jones; Anatomy, S. W. M. Jones; Bacteriology, F. H. Kelly; Pathology, A. O. Gray; Forensic Medicine and Public Health, A. O. Gray; Pharmacology, R. H. Fleming; Practical Midwifery, A. O. Gray; Practical Surgery, A. O. Gray; Midwifery, G. E. Beaumont; Surgery, C. Helm; Medicine, A. O. Gray.

Numerous certificates of merit were also awarded to other students at the close of the session.

Apothecaries' Hall of Ireland.

The following are the results of the July examinations:—

Primary Professional Examination.—Passed in Chemistry: S. Stritch, S. Ram Rao, D. Campbell. Passed in Physics: S. Stritch, S. Ram Rao, D. Campbell. Passed in Biology: S. Stritch, S. Ram Rao, D. Campbell. Completed Examination: S. Stritch, S. Ram Rao, D. Campbell.

Intermediate Professional Examination.—Passed in Anatomy: D. Campbell, S. Ram Rao, U. A. Kynvett-Hoff, C. Duckworth. Passed in Physiology and Histology: M. Burke-Kennedy, S. Ram Rao, D. Campbell, U. A. Kynvett-Hoff. Passed in Materia Medica: S. Ram Rao, D. Campbell, U. A. Kynvett-Hoff, C. Duckworth. Completed Examination: S. Ram Rao, U. A. Kynvett-Hoff, D. Campbell.

Final Examination.—Passed in Medicine: D. Campbell, J. A. M'Conochie. Passed in Midwifery and Gynaecology: D. Campbell, P. O'C. White, J. A. M'Conochie, S. Ram Rao. Passed in Surgery (including Ophthalmic Surgery): C. D. Downing, M. Keogh, J. A. M'Conochie. Passed in Medical Jurisprudence and Hygiene: S. Ram Rao, D. Campbell. Passed in Pharmacy: J. A. M'Conochie, S. Ram Rao, D. Campbell, U. A. Kynvett-Hoff. Completed Examination: C. D. Downing, J. A. M'Conochie, M. Keogh.

Medical Appointments

The following appointments of Medical Officers of the General Post Office, Dublin, have been made as from July 1st:—Central District, Dr. William Ireland de C. Wheeler; Rathmines and Pembroke, Dr. Warren; James's Street, Dr. Magennis; Clontarf, Dr. O'Connell Redmond; Phibsborough, Dr. Ryan.

NOTICES TO CORRESPONDENTS, &c.

✎ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 2s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DR. R. E. F.—Legal Notice of Defence having been tendered, you will probably hear no more of the matter. The attempt to obtain compensation by threat was too obviously evident.

LOCUM TENENS.

DR. A. G. BATEMAN, General Secretary, Medical Defence Union, 4, Trafalgar Square, W.C., writes us as follows:—"May I once again ask your readers—especially those in the Eastern Counties—who may receive an application from either 'Dr. George Covey or 'Dr. Richard Nunn for appointment of 'locum tenens,' to communicate with me before entering into any contract or placing their practices in the hands of those individuals; or, if they have already engaged such, to let me know at once."

DR. W. A. S. (Essex).—It is not difficult to appreciate the fact that chlorine and calcium are necessary for the daily regeneration of the tissues of the body, but to take these ingredients in the form of egg-shells, which has been recently suggested by certain German savants, would not commend itself to the average Britisher.

HEALTH LEAFLETS.

THE National League for Physical Education and Improvement has recently added four new health leaflets to its well-known series, which has already met with so much appreciation both by Public Health Authorities and by the over-increasing number of voluntary health workers. One deals with cleanliness in the home, another with fresh air and ventilation, while the other two contain instructions on bringing up breast-fed and bottle-fed infants respectively. All four are couched in simple and forcible language. Specimen copies will be sent on application to the Secretary of the League, 4, Tavistock Square, W.C., if a stamp is enclosed for postage.

L.R.C.P., M.R.C.S.—It would be against our rule to take sides in the dispute referred to. The point could, we think, be easily arranged if both were willing, without resort to publicity or law, and we should be pleased to act as Arbitrator if requested by both parties.

Appointments.

DAW, S. W., M.B., B.S.Lond., F.R.C.S.Eng., Surgical Tutor to Leeds University and Surgical Registrar to the Leeds General Infirmary

DIXON, GODFREY BROOKES, M.R.C.S., L.R.C.P.Lond., L.S.A., Principal Sanatorium and Tuberculosis Officer to the City of Birmingham.

DONALDSON, ROBERT, M.B., Ch.B.Edin., F.R.C.S.Edin., D.P.H., Pathologist and Bacteriologist to the Royal Berkshire Hospital

JOHNSTON, H., M.B., Ch.B.Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Newtyle District of the county of Forfar.

LEVERTON-SPRY, EDWARD, L.R.C.P.Lond., M.R.C.S., Medical Officer for the St. Kererne District by the Helston (Cornwall) Board of Guardians.

MACPHAIL, ALEXANDER, M.B., C.M.Glasg., Lecturer on Anatomy to St. Bartholomew's Hospital.

Vacancies.

Armagh County Council.—Tuberculosis Prevention (Ireland) Act.—Medical Superintendent. Salary £400 per annum, with £100 per annum for travelling expenses. Immediate application to Joseph Atkinson, Secretary to the County Council. (See advert.)

County of Devon.—Assistant School Medical Officer. Salary £250 per annum, with allowance for expenses. Applications to the Secretary, County Education Office, Exeter.

Salop Infirmary, Shrewsbury.—House Surgeon. Salary £150 per annum, with board, washing, and residence. Applications to Joseph Jenks, Secretary.

Blackburn Union.—Resident Medical Officer.—Salary £150 per annum, with apartments, rations, washing, and attendance. Applications to Chas. E. Bygrave, Union Clerk, Union Offices, Cardwell Place, Blackburn.

York County Hospital.—House Physician. Salary £100 per annum, with board, residence, etc. Applications to Fredk. Neden, Secretary and Manager.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £175 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £160 per annum, with board, furnished apartments, washing, and attendance. Applications to Medical Superintendent.

Portsmouth Borough Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Perth District Asylum, Murthly.—Assistant Physician. Salary £120 per annum, with board, laundry, and attendance. Applications to Dr. Bruce, Murthly.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 a year, with residence, board, attendance, and washing. Applications to Neville Holden, Hon. Secretary.

North Devon Infirmary, Barnstaple.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to Chairman, House Committee.

Births.

MOLLISON.—On Aug. 7th, at 26, Nevern Mansions, S.W., the wife of W. M. Mollison, M.C., F.R.C.S., of a daughter.

TA BOIS.—On Aug. 9th, at Clare Hall, South Mimms, Barnet, the wife of A. C. Ta Bois, M.D., of a daughter.

TRIST.—On Aug. 7th, at St. Columb, Cornwall, the wife of J. R. R. Trist, M.R.C.S., of a son.

Marriages.

CANE.—ENGLISH.—On Aug. 8th, at Holy Trinity Church, Orton Longueville, Leonard Buckell Cane, M.D., of the Minster Precincts, Peterborough, eldest son of the late Leonard Cane, M.D., to Margaret, eldest daughter of Marcus V. English, of Orton Longueville, Peterborough.

GRAY.—MUMMERY.—On Aug. 5th, at the Church of Saint Michael and All Angels, Bedford Park, W., Robert Walker Gray, M.B., C.M., D.P.H., Medical Officer Southern Nigeria, to Hilda Mummery, daughter of the late A. F. Mummery and Mrs. Mummery, of 105, Esmond Road, Bedford Park, W.

HUNTER.—BEALE.—On Aug. 9th, at the Parish Church, Stone, Kent, Percy Douglas Hunter, M.R.C.S., L.R.C.P., third son of Walter Hunter, Esq., of 2, Chartfield Avenue, Putney Hill, S.W., to Kate Bell, daughter of Charles Beale, Esq., of 12, Farleigh Road, N.

Deaths.

FARADAY GILES.—On Aug. 11th, 1912, at Homel Hempstead, Dorothy Mary, eldest daughter of Bernard Faraday Giles, M.D., aged 25.

GIBBES.—On July 19th, at McAlester, Oklahoma, U.S.A., Heneage Gibbes, M.D., son of the late Rev. Heneage Gibbes, of Bradstone, Devon, and grandson of the late Sir George Smith Gibbes, F.R.C.P., Physician to Queen Charlotte, aged 73. (By cable.)

JACOB.—On Aug. 16th, at the residence of her daughter, Inverness, Florence Jacob, widow of Dr. Archibald H. Jacob, M.D., F.R.C.S., I. of Dublin, aged 71.

MEREDITH.—On Aug. 11th, at St. Leonard's, John Edward Meredith, M.D., of Maidstone, after a long illness. Friends will kindly accept this, the only intimation.

RAND.—On Aug. 7th, John Rand, F.R.C.S., of Felixstowc, Love-Jace Road, Surbiton, aged 76.

ROGERS.—On the 7th inst., at Eastbank, Eltham, Thomas Lawes Rogers, M.R.C.P., in his 84th year.

SEQUEIRA.—On Aug. 9th, at a Nursing Home, James Scott Sequeira, M.R.C.S., of South Hackney, aged 84.

TAYLOR.—On Aug. 12th, at Kingston Hill, Elizabeth Ann, widow of Alfred A. Taylor, aged 82.

VEALE.—On Aug. 4th., at 18, Weighton Road, Anerley, Rachel Sandys, the beloved wife of Brigade-Surgeon T. S. Veale, M.D., aged 77.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, AUGUST 21, 1912.

No. 8.

NOTES AND COMMENTS.

AMONG the many schemes, good, bad, and indifferent, which have been put forward as the alternatives of medical benefit under the National Insurance Act, is one which, under ordinary circumstances, would be beneath our notice, but to which we may now briefly allude, as illustrating a common tendency of the present age. A certain individual, eager for notoriety, has been struck with the brilliant idea that people should do without medical men altogether, save, perhaps, in surgical emergencies, and he has, accordingly, published this illuminating suggestion in several of the northern daily papers. The "unnecessary luxury," as he calls it, of medical men may, he states, easily be dispensed with by a little more attention to food and drink and by obedience to the laws of nature. He goes on to say that many great social and sanitary reforms "owe their progress not to the physician but to the laity." Without discussing the accuracy of this latter statement it may be remarked that a sort of fascination for dabbling in physic has always existed amongst a certain class of the public, especially in those whose good intentions outweigh their intellectual faculties. Self-doctoring, self-prescribing, and self-drugging are largely upon the increase in this country, hence the success of the patent medicine traffic, but he would be a bold man indeed who would venture to assert that the death-rate is diminishing in consequence. Fortunately for the public health, there is not the slightest possibility of this grotesque alternative to the medical benefit being treated otherwise than with the silent contempt that it deserves.

Death after Vaccination; Post or Propter?

To show what lengths the opponents of vaccination will go in their endeavour to attribute all sorts of different fatalities to the performance of this slight operation, the case reported in the *Star* of August 8th may be quoted. The patient was a well-developed youth of fifteen, who had passed a Civil Service examination for the position of boy copyist. He was certified as being medically fit, with the exception that he was advised to have his teeth seen to and also to get vaccinated. The lad's father, in writing the account of his son's case, states that the vaccination was duly performed on July 5th, the usual certificate being given a week later. Meanwhile the boy had complained of headache, seemed drowsy, and there was said to be a swelling near the armpit. On the 18th he walked into a doctor's surgery and there fainted. The next day he became unconscious and was removed to the London Hospital, where he died on the 22nd without recovering consciousness. We have not

the official medical details of the case before us, but the account of the autopsy, as given in the *Star*, leaves little doubt that the unfortunate lad succumbed to heat-stroke, the fatal issue being said to have been due to cerebral hæmorrhage, while the blood-vessels were enormously congested and distended. It will be remembered that the period of his illness coincided with the heat-wave with which the metropolis was then visited. It is not stated whether any special precautions were given or carried out after the vaccination, but it is manifestly unfair to assume that death occurring seventeen days afterwards was necessarily due to the operation itself, in view of the *post-mortem* findings. But it is useless to argue with some people, and we suppose that the case of this boy, with whose parents we deeply sympathise, will be used by the anti-vaccinators as yet another instance of the terrible dangers attendant upon this simple inoculation.

Turkish Baths and the Shops Act.

THE coming into force of the Shop Assistants Act, whereby, amongst other things, a compulsory half-holiday is given twice weekly to all employees, has been attended with various difficulties in administration. Thus, a grocer having a wine and spirit licence may open his shop on the half-holiday to sell wines and spirits, but he may not sell groceries to his customers at such times. In some occupations the unfortunate assistant is in mid-air, so to speak, for he neither comes under the Act nor its exemptions. An instance of this kind is the Turkish Bath attendant, who has, so far, not been brought within the Act, inasmuch as there is no actual selling of goods. If the matter were put to proof, it is possible that the sale of refreshments which takes place in these establishments might bring them into the Act. For the present, however, the Turkish Bath employee derives no benefit from what is in principle a commendable piece of legislation. There is no apparent reason why a man thus employed should not share in the advantages society has decided henceforth to bestow upon those who do the hard work of the world. Other persons in the same social class are included in the Act, and when the attention of the London County Council and of other authorities concerned is directed to the point there should be no great difficulty in extending the Act so as to include a highly-deserving set of men.

The Turkish Bath.

TURKISH bath employees constitute a large number of men and women in the aggregate. They are able to earn good wages, and their occupation is healthy. At the same time, however, it involves extremely long hours of work,

and there is little time for the domestic and other amenities of ordinary life. The popularity of this form of bath has gone on steadily increasing for many years past, and at no previous period has the public been provided with more sumptuous and convenient baths, or with a better trained service of attendants. The value of the Turkish bath from a medical point of view is pretty universally admitted. To the town-dweller it offers a substitute for the active physical exercise that is rendered impossible to him by the conditions of his environment. To the mildly rheumatic patient it spells comfort and safety, while to the gouty it is the one rational form of prevention open to him at all times and seasons. The Turkish bath, as a matter of fact, is good for all, except at the extremes of life, and when serious heart or other organic mischief is present. The chief drawback to the busy man is the time that is required, but we know several men of affairs who take their Turkish bath with clockwork regularity; some of them, indeed, save time by taking a meal whilst in the cooling-room, where they can also write letters and send telephone messages. It seems unlikely that anyone will be able to invent a quicker form of Turkish bath.

Common-Sense Philanthropy. THE death of Miss Octavia Hill has removed from our midst one of those practical philanthropists who are essentially the product of the British character. Although her ideals were high, she made no attempt to achieve impossibilities in social reorganisation, but, taking things as she found them, worked steadily at the bettering of existing means and conditions. Her name will always be associated with the great modern movement which has had for its aim and end the elevation of the slums. One of her main principles was to insist upon the need of soap and water, the use of the scrubbing brush, the necessity of fresh air, and other commonplaces of domestic hygiene. Such matters are apt to be overworked by the theorist, who seeks an explanation of the drawbacks of slum life in an unequal distribution of wealth, or in the innate depravity of the slum landlord, with the necessary conclusion that the only effectual remedy is to be found in legislation. While no one can deny that there is plenty of room for reform in both of the above-named directions, we have in Miss Hill's lifework an object-lesson of the value of methods which appeal to the slum-dweller as a vital and indispensable part of the social problem of which he forms so disquieting a section. Place him in never so fine and perfect a model dwelling, he will quickly convert it into a den of filth and unwholesomeness, unless he carries out in practice the ordinary rules of domestic order and cleanliness.

The Slums of To-day. THE fashion of "Slumming" has not altogether died out among the well-to-do classes of society. To their credit be it said, that many good men and women go amongst the slum-dwellers with the message of hope and the gospel of wholesome living. Legislation has done much in the way of providing education, of enforcing good standards of public health, of limiting the hours of labour, of safeguarding the health of the worker, of securing him compensation for injury, and, lastly, of providing against the risks of unemployment and the disabilities of old age. Then, again, the local public health administration has immensely improved of late years, although much more remains to be done, in such directions, for instance, as the security of tenure of office by the

medical officer of health. It may fairly be said that much of this improvement has had its ultimate origin in the work of those who first paid attention to the practical needs of the slum dwellers. Among that noble band of philanthropists the name of Octavia Hill deserves to be recorded as one of the women who subordinated mere sentiment to the dictates of practical common sense, a proceeding which in the long run is the only one likely to produce results of enduring value.

Training for Tuberculosis Officers.

Now that the public have begun to realise that tuberculosis, if it is to be finally stamped out, must be fought by the active co-operation of the masses with the medical profession, it is interesting, and not a little amusing, to hear the views of the sundry self-constituted authorities upon the question. One writer to the papers, hailing from the aristocratic quarter of Grosvenor Square, is convinced that consumption may be cured by attention to the proper method of respiration, and boldly asserts that "not a single medical school pays the slightest attention to the study and practice of breathing," which he thinks is a grave scandal! The value of full and deep breathing as a means of securing a better aeration of the blood is fully recognised by medical men, but no one would seriously maintain that consumption may be "cured" by breathing exercises alone, except an extreme physiculturist. What is more urgently needed at the present moment is, as Sir William Osler has recently pointed out, some form of special training for tuberculosis officers, for which class of practitioner there is likely to be a brisk demand in the near future. A three-months' course of instruction in the diagnosis of early phthisis, the methods of work in a tuberculosis dispensary, the technique of the administration of tuberculin, etc., would provide a good scheme of instruction for those desirous of taking up this work. Even if differences of opinion do exist as to the relative advantages of sanatorium, tuberculin, and other modes of treatment, there is nothing to prevent the judicious employment of all of them in cases that are respectively suitable for each.

LEADING ARTICLES.

THE FRENCH POPULATION QUESTION.

THE custom of narrowly restricting the number of children in the family has prevailed for many years virtually among every class of the French people, even the peasantry of some Departments, who formerly displayed normal fecundity, having adopted the fashion of limiting their offspring to two or three. Among the mass of the people the family now practically never numbers more than three, and it is among the true *elite*, the physiologically best bred, that the numbers are smallest. The effects of this custom from the eugenic point of view, have not yet been enquired into. A gigantic system of artificial selection has, however, been carried on for at least a hundred years, but whether this has tended to produce a superior or inferior stock remains to be proved. If it is the rule that the first born are the best of the human brood, then evidently so far all may be well; but if as a rule the best samples, physically

and mentally, are to be found among the later born, and if with less interference with natural selection these would provide the seed of the race, it seems clear that deterioration must have gone on. No writer of authority doubts that the births are regulated by the voluntary acts of parents. Many parents agree to have no children; the majority decline to produce and rear more than suits their own egoistic purposes. In this way, parents are no doubt saved from strenuous effort and anxiety, and whilst the girls are made sure of matrimony by an adequate *dot*, the boys are guarded from the battle of life which has been thought so good for the formation of high character. In whatever way the problem has been regarded, from the personal or from the eugenic point of view, the broad results brought about have for long been a cause of anxiety to French men of science and statesmen. The population remains stationary; in some Departments the deaths exceed the births, and the numbers—between 39,000,000 and 40,000,000—have been kept up during the past forty years only by immigration from Italy, Switzerland and Germany. France, with the most splendid climate, and the most fertile soil in Europe—a soil capable of supporting many more millions than at present subsist upon it—has not enough men for her home requirements; she has none to spare for the vast oversea territories, misnamed colonies, which she has acquired within recent years. Great areas of these territories—the highlands of Madagascar, for example—are suitable for people of European blood. In Tunis, Algeria and Morocco, French protectorates or colonies, the bulk of the white population is not French but Italian, Greek, and Levantine. In view of recent statistics, which show for last year a falling off of 32,869 in the births as compared with those of 1910, it is not perhaps surprising to learn that the French Government has now appointed a Commission for the purposes of investigating the causes of the decline, and suggesting remedies. The population of Germany in another decade will be more than double that of France, a sufficiently suggestive fact bearing on the problem of national defence. M. Bertillon, in emphasising all the facts, points out the importance of immediate action if France is to maintain her position in the world. He shows that whereas a century ago 27 per cent. of the population of the Great European Powers were French, to-day the proportion is only 11 per cent. Formerly French was the most widely-spoken language; to-day it is the mother tongue of only 45,000,000 as compared with 100,000,000 who speak German and 130,000,000 who speak English. M. Bertillon suggests an appeal to patriotism, and urges that Frenchmen must be taught to regard a child as a burden which its father supports for the benefit

of the whole community. But as every intelligent Frenchman has for forty years been alive to the fact that the safety of his country depends mainly on population, and has yet refused to make the sacrifices called for in rearing, on an average, more than two children, the efficacy of this appeal must remain doubtful. It is urged that the family should consist of at least three children—two to fill the places of the parents when they die, the third to fill the gaps caused by those who die before attaining adult age. In order to promote this end it is proposed to arrange a reduction of taxation upon fathers of three or more children, in proportion to the number of living offspring. It is further suggested that the laws of succession should be modified and formalities of marriage simplified; that mothers of large families should be assisted in various ways; that especial provision should be made for widows left with children; and that among public servants candidates for employment by the State who have children should be considered as eligible in proportion to the size of their families. The result of the enquiry by the new Commission cannot be without importance to the people of these islands, seeing that our present falling birth-rate, if continued, will bring us within a very few years into a position exactly similar to that of our neighbours.

ALCOHOL AND TOBACCO.

OF all revolutions in our social and domestic habits, that which has decreed the rational as against the excessive or irrational use of alcohol is perhaps the most far-reaching. In some form or other mankind has always craved for the narcotic poisons which Nature, curiously enough, has often placed, so to speak, ready at his elbow. The Mohammedans, who eschew alcohol, substitute, on the other hand, opium, coffee and tobacco, which they consume in enormous quantities. The very existence of the "drug habit," in point of fact, marks the survival in an individual of faulty control of the deeply placed instinct which leads man to turn to narcotics. Of late years a great change has undoubtedly come over the drinking habits of the nation. Nowadays it is considered disgraceful for a man to be seen under the influence of alcohol, and the domestic consumption of wine and spirits has enormously decreased. At clubs or hotels or public dinners it is now a common experience for those at luncheon or dinner to drink nothing stronger than water. The drink bill of the nation is therefore steadily diminishing, although there is still room for a great deal of improvement, especially among the working classes. The life of the average labourer is one of toil and of hard living on scant means, so that it is only natural he should seek some alleviation in alcohol. A newspaper discussion has been taking place lately upon this point. It has been estimated by

a country clergyman that the average labourer pays in indirect taxation £5 2s. 11d. per annum, and of that sum £3 14s. 8d. is contributed to the Exchequer on account of beer and tobacco. On the basis of these figures a brother clergyman exhorts the labourer, "for his health's sake, his pocket's sake, and his children's sake, to abstain from the poisonous luxuries—alcohol and tobacco." While agreeing with the general tenour of this advice, we cannot help reflecting on the differences of lot in him who gives and him who takes that wholesome exhortation. Take, for instance, the proportionate time spent in labour, rest and recreation, the social and intellectual resources of relaxation, the proportionate income, and so on. If alcohol be needed by either man, there can be little doubt as to which brain and body needs physiological stimulation, or even at times the higher degrees of narcosis. An analysis of the position, in fact, brings us round to the desirability of improving in every way the opportunities of the labouring classes so that they may be assured of the chance of decent competency. The temperance worker is apt to be somewhat narrow in his outlook, and to seek in repressive legislation a remedy for all the social evils he sees around him, due to excessive drinking. As a matter of fact, he might accomplish much by establishing statutory standards of purity and strength in alcoholic beverages. Much of the damage to health is undoubtedly due to the sale of beer and spirits containing crude and harmful impurities. Various absurd restrictions in favour of the drink trade should be abolished forthwith. A license, for instance, should be granted to all restaurants or eating houses where customers could obtain ale or wine with their meals. Then there is the futile restriction which prevents persons holding an off-license from selling less than certain quantities of alcoholic beverage. For instance, such a person cannot sell less than three dozen of bottled ale. It may, of course, be argued that the sale of single bottles would be greatly multiplied if the sale were unrestricted, but, on the other hand, it is absurd to assume that a man would be more likely to be temperate if saddled with three dozen bottles of beer instead of, say, half a dozen. Then, again, the grocer is prevented from selling half bottles of spirits, although that right is granted to the licensed victualler. Many persons who now buy, perforce, a whole bottle of spirits, would prefer to purchase a half bottle. It would be well if some philosophical friends of the temperance question could arrange to have these matters brought forward in Parliament. It is unlikely that the consumption of alcohol as a national habit will cease for many generations, and the best results will be secured only by the adoption of fair and reasonable principles of control. The attitude of the reformer who speaks of the poor man's beer and tobacco as "poisonous luxuries" is hardly likely to secure the sympathetic reception which his propaganda undoubtedly merit. As to tobacco,

there are no signs of a decreasing consumption, nor can any such consummation be anticipated while mankind is constituted upon its present basis. All the narcotic poisons in ordinary daily use—caffeine, theobromine, nicotine, alcohol—are harmless in small quantities and fatal in large. As regards the consumer, if he is not sure of his powers of control, he had better abstain altogether. Otherwise, each one has its appropriate place in the scheme of human life. The whole question, from a philosophical point of view, narrows itself down, more or less, to that of the well-worn adage which warns us against the good servant that makes a bad master.

CURRENT TOPICS.

The Notification of Acute Poliomyelitis.

An Order was issued last week by the Local Government Board under Section 130 of the Public Health Act, 1875, rendering general in England and Wales the notification of acute poliomyelitis and cerebro-spinal fever. In a circular accompanying the Order it is recalled that on December 12 last the Board suggested to local authorities the desirability of notification, and in response to that suggestion many authorities have taken steps under the Infectious Disease (Notification) Act, 1889, to make these diseases notifiable, but this action has not been taken universally. The Board, having been advised that more general action is now desirable, have issued the Order referred to above, so that all cases of these diseases may at once be brought to the notice of the public health authorities. A special form of certificate for cases of acute poliomyelitis and cerebro-spinal fever has not been prescribed, but the age and sex of the patient and the date of the onset of the disease are to be given, in addition to the information required in the certificate prescribed for the purposes of the Act of 1889. In districts in which these two diseases are already notifiable under the Act of 1889 the medical practitioner will notify under that Act and not under the Regulations. He will, however, be required under the Regulations to give the additional information referred to. The Board request local authorities to send them from time to time full particulars of cases notified and of the arrangements made for the examination of cerebro-spinal fluid and other pathological material, and for the treatment of patients. The Order will come into force on September 1 next and should prove of material assistance in dealing with these two diseases.

Colour Blindness at Sea.

THE practical importance of the ability to recognise coloured lights for naval officers and seamen is universally recognised. It is interesting, therefore, to note that in a Blue Book issued last week containing the minutes of evidence taken before the Departmental Committee on Sight Tests, Dr. W. H. R. Rivers suggests that a colour-blind person may possibly, owing to his development of powers other than colour sight, be able to recognise the three lights used at sea sooner than a normal person. He is enabled to make use of other criteria, such as differences of hue, of luminosity, and of saturation. A red and green light, which are wholly different to the normal eye, may also be wholly different, on account of their difference in luminosity and saturation, to a person who confuses red and green, and of these saturation is especially important. Taking the lights used at

sea as examples, the white light is generally yellowish, and the red light also yellowish, and therefore these two lights will appear in the same hue to the red-green blind person, but they differ wholly in saturation. While the colour in which the red light appears has a very high degree of saturation, the white light will obviously have a very low degree of saturation, and it is probably as a result of this difference of saturation that the colour-blind person never confuses these two lights. The recognition of the green light is a more difficult matter for the colour-blind, partly on account of the greater variability in the hue of the green lights used at sea. The colour-blind can often distinguish differences of luminosity and saturation more delicately than the person with normal colour vision. This increase, it is suggested, may be so considerable that colour-blind persons may actually be able to see colours which are so faint as to be totally invisible to the normal eye. The international standardisation of the lights used at sea is advocated, and it may be noted that the choice of a blue-green light of constant hue for the standard green light has already been taken by Great Britain and Germany, and possibly by many other nations.

The Tuberculosis Campaign.

SUPPORTED by a closely-reasoned statement, Sir William Osler publishes an appeal for organisation in the campaign against tuberculosis. He suggests the formation of a general staff, which shall control the Government funds, direct the campaign, plan the education of doctors, nurses, and the public, organise research, and act as co-ordinating centres for the manifold activities engaged in the work. He advocates a comprehensive scheme on lines suggested by the Astor Committee, co-ordinating the various agencies. At the head he would place the Local Government Board, which he describes as an effective working machine, directed by "a man both sympathetic and intelligently enthusiastic in all that relates to tuberculosis." He urges that the energies for research work should be concentrated in one large laboratory. Sir W. Osler believes that the fighting line will centre about the dispensaries. He points out that at present no provision exists for the training of their officers, and shows how easily this could be arranged for in existing institutions. He strongly urges the linking of tuberculosis work with existing hospitals and dispensaries, and for the following reasons: Many patients apply who are not tuberculous and can be turned over promptly to the proper departments. Many cases of bone, gland, and other forms of local tuberculosis need surgical advice and treatment, which they can receive while attending the special dispensary. Patients applying in other departments and found to be tuberculous can be transferred at once. Doubtful cases, patients with abdominal, gland, and bone disease, early forms of pulmonary tuberculosis, may be admitted to the wards at once for observation. For the sake of the public the members of the staffs of general hospitals should not be deprived of the opportunity of seeing so important a disease as tuberculosis.

Venereal Prophylaxis.

THE prophylaxis of venereal diseases to be efficient must include social and individual preventive measures. Two important papers have recently appeared on this subject, one, by Howard A. Kelly, M.D., of Baltimore, which appeared in the last issue of the MEDICAL PRESS AND CIRCULAR, deals with a social method of prevention; and the other, by Dr. Bachmann, of the United States Navy, con-

siders the individual side of the question (*Medical Record*, August 3rd, 1912). Dr. Kelly passes under review the various attempts to segregate prostitutes in Brussels, Berlin, Norway, Sweden, Italy, Denmark and Japan, and points out that the chief authorities in these countries are convinced that segregation has nothing but a baleful effect upon public morality and advocate that the system be discontinued. Moreover, the regulation of prostitution by the State and the medical examination of prostitutes have absolutely no effect, except a pernicious one, on the prevention of venereal diseases. Dr. Kelly holds that the only method of dealing with prostitution is by extermination. As an ideal condition cannot come in a day, to cope with venereal disease we must turn our attention in the meantime to individual preventive measures. If the medical profession would only realise the importance of Metchnikoff's discovery that a 30 per cent. calomel ointment relatively protects against syphilis, if they taught the public so, and if such individual prophylactic measures as are used in the Navy in regard to gonorrhœa were instituted, these diseases would claim fewer victims every year amongst laymen as amongst the men in the Navy. The only person an individual has any control over is himself, and if doctors would teach prophylaxis to individuals, they would gradually decrease the number of victims to venereal disease, whilst they and others use every effort to abolish or limit the great social evil of prostitution. The latter should be done, and the former not left undone.

PERSONAL.

DR. C. WILFRED VINING, M.D., B.S., M.R.C.P.Lond., D.P.H., has been appointed Assistant Physician to the Leeds General Infirmary.

MR. DONALD DUFF, F.R.C.S.Edin., F.R.F.P.S. Glasg., has been appointed Assistant Surgeon to the Glasgow Royal Infirmary.

DR. H. O. WEST, of Queen Mary's Hospital for Children, Carshalton, has been appointed Tuberculosis Officer by the Kent Insurance Committee.

MR. EDWARD D. DAVIS, F.R.C.S., has been appointed to the recently created post of Assistant Surgeon to the Throat, Ear and Nose Department at Charing Cross Hospital.

SIR WILLIAM TURNER, K.C.B., Principal of Edinburgh University, has been created a Knight of the Prussian Order of Merit, in recognition of his eminent services to medical science.

DR. J. C. M'WALTER, of Dublin, has been elected Deputy-Governor of the Apothecaries Hall of Ireland, and a member of the Court of Directors of the same Corporation for the ensuing year.

SIR THOMAS CROSBY, M.D., Lord Mayor of London, has been appointed Hon. Colonel of the 1st London Brigade, R.F.A., during his year of office, and has received His Majesty's Commission in that capacity.

WE are asked by the *Deutsches Zentral Komitee für Ärztliche Studienreisen*, to announce that an educational tour for medical men will start from Hamburg on September 7 for the United States and Canada. Lectures will be delivered on board the ship, so that pleasure and educational advantages are united. About 250 German doctors are expected to take part in the tour, and English practitioners desirous of joining should address the Committee, 134B, Potsdamerstrasse, Berlin.

FRENCH CLINICAL LECTURE

ON

THE TREATMENT OF BILIARY VESICULAR COLIC.

By DR. PIERRE LEREBoullet,

Medecin des Hopitaux de Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

It would seem that, till recent years, the treatment of biliary lithiasis was wholly directed to the expulsion of calculi from the gall-bladder. If such treatment be justifiable when these are capable of passing into the intestine, it is ineffective, and even dangerous, when the calculi cannot enter the cystic or the choledic duct, or risk obstruction of the same. But there are many cases in which these conditions are realised. (a) Besides the classical hepatic colic, with its well-known syndrome of paroxysmal pain, followed by slight jaundice—due to temporary obstruction of the common choledic duct, and in which examination of the evacuations suffices to prove the passage of the calculus into the intestine—there is another type, the *vesicular colic*; and in this the pain is not the expression of the migration, but of the presence of the calculus in the gall-bladder. This form, to which Professor Gilbert has specially drawn the attention of physicians in recent years, is even more frequent than the classical hepatic colic. The more we see of patients affected with biliary lithiasis, the more highly we appreciate the practical interest of knowing this fact well. For we would otherwise oftener suffer from the illusion of seeking to confirm the migration of calculi after vesicular colic than succeed in pursuing the same after the classical hepatic colic. On the contrary, we should endeavour to secure the tolerance of the gall-bladder. By so doing, we are merely following the route indicated by nature, since it is in this way that patients affected by biliary lithiasis are usually cured. And Professor Gilbert—who, since 1898, in conjunction with L. Fournier, has brought into prominence the clinical characteristics of vesicular colic—has repeatedly insisted on the therapeutic means which should be employed in order to realise this toleration of the gall-bladder. These we shall now briefly recall.

CLINICAL FEATURES.

The clinical characteristics of vesicular colic lend themselves to ready recognition. The pain is usually less violent than in the true hepatic colic, less paroxysmal, and more permanent. It is usually referred to the region of the gall-bladder at the level of the cystic point, but occasionally to the epigastrium, and may radiate to the scapular region. It occurs spontaneously, but is elicited, or increased, by pressure over the situation of the gall-bladder; and is often accompanied by nausea and vomiting. On the other hand, the icterus is usually either absent or limited, except in very acute cases, to a very slight sub-icterus, which is always acholuric. There is no migration of the calculus—except in very rare cases—so that the crisis is not followed by appearance of concretions in the stools. The temperature often remains normal, or is but slightly elevated; but in some cases fever is present, with or without thermal inversion. Then, while in cases of true hepatic colic examination of the gall-bladder may reveal nothing particular, in the cases under discussion it may be distinguished on palpation, and in one of two forms: Sausage-shaped—elongated, cylindrical, and readily

definable; or globular—with varying degree of increase of volume, in which case it may be mistaken for a tumour or hydatid cyst. But, in either shape, the cystic swelling constitutes a condition which gives considerable aid in the diagnosis of vesicular colic.

The characteristic syndrome of vesicular colic usually persists for a long period; and, during a lapse of weeks, or even months, tends to reappear very readily. Thus, it may constitute a condition of *mal biliare* (Gilbert); and it is when that condition has been established that various complications supervene: especially such nervous derangements as delirium, hallucinations, and even convulsions—which appear more frequently in such cases than in ordinary hepatic colic.

Vesicular colic, when repeated, may be followed, secondarily—as a result of arrest of the calculus at the entrance of the gall-bladder—by the formation of a hydro-cholecyst of variable dimensions; or, on the other hand, the inflamed gall-bladder may undergo atrophic contraction upon the contained calculi, with sclerosis—which, in turn, leads to the development of a sub-hepatic peritonitis, accompanied by permanently recurring pains of more or less vivid type. (a) But whether the vesicular colic leads to such an anatomical state—objectively definable—or merely becomes the source of secondary nervous phenomena, by the persistent pain which it produces, it is a condition which calls for treatment. And, in deciding the course of treatment, we should remember that it is a function of the presence of calculi, much more than of inflammation of the walls of the gall-bladder. Nevertheless, the cholecystitis has often been credited with the origin of the painful symptoms. But this inflammatory theory, notwithstanding the favour with which it has often been treated, does not seem to be based on demonstrable arguments. Unquestionably, the cholecystitis appears, after an interval of various length, subsequent to the symptomatic pains, and it is even absent in many cases in which the vesicular colic is manifest; thus everything tends to show that, as in cases of non-migratory vesical calculi, the pains are specially tenacious, and the biliary calculi provoke the syndrome of vesicular colic by their presence and mobility in the cavity of the gall-bladder.

TREATMENT.

The treatment should be inspired by this fundamental view. To endeavour to remove the calculi by purgatives and cholagogues is to proceed in a direction opposite to that of the desired result. The calculi are usually too large for the cystic duct, or, this adapts itself badly to their passage. Accordingly, such therapeutic procedures aggravate the symptoms; the calculi are likely to become lodged in

(a) It may sometimes be difficult to establish a diagnosis between the pains of vesicular lithiasis and the permanent pain connected with adhesions of the gall-bladder to the adjacent intestine. But, in the latter case the pain is not at all affected by rest or general habit, and such negative effects may aid in forming an opinion. I have thus been enabled, in a recent case, to affirm the existence of perivesicular adhesions, which was verified by operation; division of these had the effect of causing the disappearance of the pains.

the cystic or common choledic duct, and thus give rise to a chronic obstruction; in every case the benefit is nil. Doubtless, we may by an early operation remove the gall-bladder and its calculi, and thus permanently suppress the source of the malady; but this treatment should not be made a rule, and should be resorted to only when we cannot establish vesicular tolerance. Now, observation proves that medical treatment, as formulated by M. Gilbert, secures this result in most cases.

Treatment of the Paroxysm.—The medicaments are here of less importance than rest and general treatment. *Absolute rest* in bed should be arranged for as soon as the nature of the case has been recognised. The gall-bladder may be treated locally by warm, moist, emollient applications; or by local unction of salicylate of methyl, or of amyl—which seem to produce a certain analgesic effect. The application of ice to the vesicular region may alleviate the pain, especially when cholecystitis also exists.

The *diet* should consist of *skimmed milk*, taken in small quantities at frequent intervals. Thus, there may be given progressively increasing quantities—up to two and a-half or three and a-half litres in the course of twenty-four hours—with or without the addition of lime-water. If there be much nausea at first, and the patient can swallow but little, he usually accustoms himself to take a sufficient dose rapidly. The object of this *régime* is easily comprehended. In the normal state, the flow of bile into the intestine is intermittent, while the secretion is continuous; the gall-bladder is filled in the intervals between meals, and empties itself at a definite time after these. Thus we may believe that, under the influence of a nearly continuous alimentation, as recommended by Gilbert to his patients, the physical function of the gall-bladder is modified, and the flow of the bile becomes continuous as the digestive process—as a matter of fact the gall-bladder remains empty in the herbivora, who are continuously feeding. When milk is badly tolerated—which rarely happens—we may try to obtain the same result by the use of *kéfir maigre* (of skimmed milk), which is very easy to digest (Gilbert and Chassevant), or some other form of liquid aliment, taken frequently in small quantities. A form of dietary which, like the above, produces a cessation of the alternating fulness and emptiness of the gall-bladder is very beneficial, leading, on the one hand, to cessation of the inflammation and tenderness of the gall-bladder; and, on the other, to the non-displacement of the calculi.

But this *régime* may not produce its effects till after some days; and, besides, it may be difficult of adaptation on account of nausea or vomiting. We should in such cases adopt a sedative medication at the beginning of the crisis. Besides the local applications, suppositories or sedative lavements may be used. Suppositories may be prepared from the following formula:—

Thebaic extract,	} āā 0.03 centigr.
Extract of belladonna,	
Cacao butter,	

Make into one suppository.

It is often more practicable, and takes less time, to give a *lavement* of *antipyrin* and *laudanum*. As M. Gilbert has suggested, we may give the patient packets of *analgesin*, of 50 cgrs. each, and *laudanum*; with instructions to use, at the beginning of each paroxysm, two or three packets of the *analgesin*, and from 10 to 20 drops of *laudanum* in a glass of warm water: to be given in form of lavement, and retained. The effect on the pain and the secondary nervous phenomena will be manifest.

When neither suppository nor lavement produces a sufficiently sedative effect, a *hypodermic injection*

of *morphin* may be employed—remembering that the tenacity of some cases of vesicular colic may call for too frequent repetition, and make us dread *morphinomania*—while entertaining a corresponding dread of its use in certain neurotic and cardiac cases. But with those reservations, the use of *morphin* and its adjuvants is desirable in vesicular colic, and the idea of a treatment which rapidly relieves the pain forbids us to neglect this therapeutic remedy, when we can see beforehand that its employment will be limited to a few days.

As soon as the pain has ceased, or has considerably diminished, we may try to improve the diet. But it is preferable to continue the milk cure from fifteen days up to three weeks; to this we may add milk porridge, broths, thin soups, pastes in moderate quantity, cooked fruits—arranging so that the patient may have a repast four or five times a day. Then we can gradually increase the quantities—having regard to the alimentary *régime* of all hepatic cases, from which must be excluded yolk of egg and fats (especially cooked fats), on account of the readiness with which these, on account of difficulty of digestion, tend to produce new crises. This *régime* should be accompanied by the use of medicines. But, while we are ready to provoke the expulsion of calculi with the known use of many cholagogues—in the foremost rank of which we would place olive oil and biliary opotherapy—the action of drugs on vesicular colic in its declining stage is relatively limited. Above all things, we must avoid the use of too powerful cholagogues. At most we can only employ those which can, in feeble doses, modify the biliary secretion, and secure for it a more regular and easy evacuation. Of this number is *boldo*, which may prove useful in the form of tincture, in doses of 20-30 drops per diem; fluid extract of *combretum*, and other mild cholagogues may also be recommended. On the other hand, we should be cautious in the use of purgatives: sodium sulphate, calomel, etc. Biliary opotherapy would certainly in strong doses have too violent an expulsive action; but in moderate quantity, and carefully watched, it may give satisfactory results; and I have seen it help to ameliorate the state of certain victims of lithiasis when administered in the decline of the crisis, and for eight or ten days. Hepatic opotherapy may likewise be of use, especially when signs of hepatic insufficiency exist (which are frequent in the decline of the crises of hepatic colic, as MM. Gilbert and Castaigne have shown).

Finally, in association with vesicular colic often arises, as in every case of biliary lithiasis, the question of the alkaline cure. This is often too active, and, when employed too vigorously, it may exasperate the crisis, as I have seen in a number of instances. On the other hand, when used circumspectly, it may modify some cases of biliary lithiasis to good purpose. If necessary to be careful at Vichy in the use of such a water as *Grande-grilles*, the use of a less active one, such as that of *Celestins*, with diminished quantity of ingestion and simultaneous employment of prolonged thermal baths, seem, as Linossier has shown, to present no inconvenient results, while exercising a useful sedative action. In absence of the alkaline cure, the less irritating cure of Vittel, or the still pleasanter one of Evian may be recommended after the crises. At the same time, those various hydro-mineral cures should be carried out with great prudence, and stopped when they renew or exasperate the painful crises.

In many cases, rest and diet, with anodyne remedies, and the others which I have here indicated, suffice to cause the disappearance, more or less rapidly, of the pains and objective signs of hydro-cholecystitis. When we realise the toleration

of the gall-bladder for calculi, this result should lead us to dispense with surgical treatment. But it is not less true that surgical intervention may be demanded when persistent cystalgia follows prolonged methodical treatment, or when there is a repetition of the paroxysmal crisis at brief intervals; or nervous complications occur, or on the appearance of a secondary cholecystitis. This operation usually consists of a cholecystectomy, with or without biliary drainage. It has been perfected within the past few years, and offers little risk. Accordingly, young subjects may be treated surgically, when their crises resist the medicinal methods already enumerated. Such a sequence is, however, rare; as the medical treatment is habitually followed by cure. Nevertheless, when the indications for operation appear they are more clearly defined than in cases of obstructive icterus; for in the latter we may always hope to clear out the biliary passages by energetic cholagogue medication, and are accordingly led to postpone the moment of operation; whereas in obstinate vesicular colic, even when obstruction and biliary infection are absent, the repetition of the pains may prove a formal indication for operation, when a well-directed medical line of treatment has failed in its effect, for it would be an illusive hope to try to assist the expulsion of calculi.

We thus see the practical importance of recognising and bearing in mind the fixed clinical features indicated by Professor Gilbert, the existence of vesicular colic, and the treatment which he has recommended—which takes account, not of the expulsion of the calculi, but of vesicular toleration.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by J. D. Mortimer, M.B., F.R.C.S., Anæsthetist, Royal Waterloo Hospital, Throat Hospital, (Golden Square), St. Peter's Hospital, &c., Instructor, Medical Graduates' College. Subject: "On Selecting the Anæsthetic."

ORIGINAL PAPERS.

A NOTE ON EPIDEMIC DIARRHŒA.

By JOHN ALLAN, M.D., D.P.H.

At this time of the year the question of preventive measures in epidemic or summer diarrhœa is always to the fore. Two years ago I discussed in the *British Journal of Children's Diseases* (March and April, 1910) various ætiological factors and methods of prevention in connection with this disease, and I laid stress on the value of education. At that time I compiled a leaflet which I suggested as suitable for distribution, and the quotation of this leaflet may not at present be inopportune.

PREVENTION OF EPIDEMIC (SUMMER) DIARRHŒA.

Each year during the hot weather in summer and autumn, a large number of infants are attacked by a serious disease called summer diarrhœa, and many of them die from this disease. The disease, though dangerous, can to a very large extent be prevented, and it is earnestly hoped that mothers will take precautions to save their babies' lives.

There is good reason to believe that the *common house-fly* is a very important agent in spreading the disease, and you are requested to make every effort to keep the fly out of your house. Remember that the fly feeds on, and breeds in, all sorts of decomposing filth, such as stable manure, decaying garbage, etc.; that it may carry away some of this filth on its legs and body, and may be covered with millions of death-producing germs; that if it afterwards settles on food, and especially milk, that will be contaminated, and it is very dangerous to give

such polluted milk to your infants. Therefore, use fly-papers in the warm season. Keep your windows closed, and do not allow your door to stand open all day. Store the milk in clean, covered dishes in some place to which flies have not access, and do not keep your food in any room near a privy, drain, etc. Burn all animal and vegetable refuse, such as fish-heads, bones, tea-leaves, potato parings, etc. Do not throw such refuse into your backyard, or place it in uncovered ash-bins. Keep your house and outdoor premises clean, and especially do not permit dust to collect in the apartment where your food is stored. Dust in every form is dangerous to health, and for removing it wet cleansing is preferable to dry. Do not allow sinks, drains, etc., to become choked. Report at once to a public health official any nuisance, such as choked drain and any manure-heap in the neighbourhood which is attracting large numbers of flies.

Bear in mind that the fly-season is the diarrhœa season, and remember that absence of filth and dust means absence of flies.

BWARE OF THE FLY.

Very few babies who are fed entirely from the breast die of this disease, and therefore you are strongly urged to suckle your infants at the breast. If you cannot give your child sufficient nourishment by this means, do not take it off the breast. *It is far better to feed from the breast and by bottle alternately than to feed by bottle only.*

On no account wean your infant during the hot months of July, August, and September. If your breast-milk has become scanty, continue to give your infant this as much as possible, and make good any deficiency by using cow's milk. Avoid giving condensed milk (especially the cheaper brands) and patent foods, and never feed your baby on anything that is going.

When cow's milk is employed, the milk should be boiled when it comes into the house, and kept in the coolest place. Keep the baby's bottle scrupulously clean, and reject at once any milk which smells sour. Use only boat-shaped bottles. Never employ bottles with long tubes, which are always dangerous. Thoroughly wash the feeding-bottle after each meal, and see that the nipple is turned inside out and well scalded.

Do not give your infant a "dummy-teat" to suck.

Never neglect any case of diarrhœa, but obtain medical advice at once. Always stop giving milk, and until the doctor arrives give nothing but boiled water or white-of-egg water.

Try to prevent any spread of the disease. Never leave soiled napkins, etc., lying out, but place them in boiling water or disinfectant, and always carefully cleanse your hands before preparing any food. Take the infant daily for an outing in the open air, and be careful not to overclothe the child.

MOTHERS, PROTECT YOUR INFANTS.

THE EFFECT OF CERTAIN CARDIAC REMEDIES ON THE ARTERIAL PRESSURE.

By JAMES BURNET, M.A., M.D., M.R.C.P. EDIN.

Physician to the Marshall Street Dispensary, and Lecturer on Practical Materia Medica and Pharmacy, Edinburgh: Examiner on Materia Medica and Therapeutics to the University of Aberdeen.

THERE is no doubt whatever that a few careful observations on the effects of drugs at the bedside are of far more practical value than hundreds of laboratory experiments on healthy animals. I have always maintained that we can never fully realise the true action of any particular drug until we have observed and recorded the effects of its administration under conditions of disease.

It is impossible to estimate the number of comparatively useless drugs which are year after year foisted upon the profession as the result of laboratory experiment, coupled in some cases doubtless with a few hasty and unsubstantiated observations at the bedside. We all remember when potassium iodide was regarded as an agent which lowered the blood pressure directly. It has been shown by various observers, Stockman and myself (a) included, that this drug does not lower the arterial pressure at all. There is, in statements made regarding drugs, a tendency to repeat, parrot-like, views regarding their actions without any attempt at original corroboration or refutation of these. In view of this fact I determined, some six years ago, after working out the effects of iodides on blood pressure, to test the effects of certain cardiac remedies in this direction. The drugs I experimented with in this connection were digitalis, strophanthus, squills, strychnine, and caffeine. In approaching the subject I determined to dismiss from my mind the biased opinion formed by the teaching gained from the literature of these drugs. I therefore started out with a clean sheet, as it were. For the time being I preferred to be utterly ignorant of the effects of these drugs on the arterial pressure, and set to work, therefore, as a pioneer in my investigations. In the remarks I am about to make it must be distinctly understood that, had I had access to a larger series of cases and more assistance in carrying on my observations, which had to be made single-handed, often at great sacrifices of time, I would have been able to collect a much larger amount of evidence. At the same time I feel justified in placing on record my results that others, with greater opportunities and with more clinical material, may confirm or refute my observations. In estimating the pressure I always employed Martin's modification of the Riva-Rocci sphygmomanometer, and contented myself with observing the systolic pressure only in the usual way. I made a few observations with an aneroid instrument, but had to abandon it as I found its readings varied from time to time, often to a very considerable extent.

The first remedy I investigated was digitalis. This I employed as the tincture, the effectiveness of which I previously tested in its power to reduce the pulse-rate and strengthen the heart-beat. Incidentally I may state that at first I had great difficulty in obtaining a reliable preparation, and had to discard several samples as being absolutely inert. During the past six years I have tested the effect of tincture of digitalis on the arterial pressure in twenty-five cases of disease, including such conditions as mitral incompetence, aortic incompetence, anæmia with palpitation, arterio-sclerosis, tachycardia after influenza and exophthalmic goitre. In none of these cases was there any effect whatever observed on the blood-pressure even when the drug was given in doses of fifteen minims every four hours. In some cases the blood-pressure registered 160 min. or over, but even here there was no tendency to its increase. On the contrary, in one case of chronic interstitial nephritis with marked arterio-sclerosis and emphysema the patient's condition greatly improved after the administration of tincture of digitalis in 10-minim doses three times a day

for several weeks with intermissions of three or four days. Incidentally I observed that greater benefit usually resulted when the drug was given in large doses (*i.e.*, 10 to 15 minims) than when it was administered more sparingly.

I also tested the action of digitalis on a few healthy individuals, or at least healthy so far as their cardio-vascular condition was concerned, myself included. My own arterial pressure was found to vary little from 120 mins., and even when I took as much as 15 mins. of tincture digitalis every four hours it was found that the mercury column did not alter, nor did I experience any diuretic effect from the drug. This is interesting, as I am extremely susceptible to drugs, small doses usually producing effects which much larger amounts would be required to induce in other individuals.

The result of these experiments showed that even from the outset of its exhibition digitalis had no effect whatever upon the arterial pressure. The action of digitalis as a diuretic cannot, therefore, be explained as due to a rise in blood-pressure. It must, I think, be entirely attributed to improvement in the general circulation so that any venous stasis in the kidney is relieved and the arterial blood-supply to that organ is re-established. This probably explains why digitalis never produces diuresis in individuals with a normal and healthy circulatory apparatus.

In carrying out these clinical experiments it must be carefully borne in mind that statements have been made, on the strength of laboratory experiments, that when digitalis is given in large doses the output from the heart may be so much diminished as actually to produce a fall in the arterial pressure. My observations show that no fall results in any case, no matter what amount of the drug is given—*i.e.*, up to 15 mins. for a dose. The only fault, if fault it can be termed, in my observations is found in the circumstance that these were not prolonged over lengthy periods. In most cases they did not extend beyond ten days, and only in two cases was I able to keep the patient under observation for periods of six and eight weeks respectively. To my mind, however, this fact is of little consequence, as the rise in arterial pressure produced by digitalis is always said to be greatest within the first few days of its administration.

Strophanthus was another remedy with which I carried out seven sets of observations. All the cases suffered from valvular lesions. This drug is stated to raise the blood-pressure without producing much peripheral vaso-constriction. I found that a reliable tincture of strophanthus was even more difficult to obtain than of digitalis. My results with this remedy are, it must be admitted, drawn from too small a number of cases to enable any dogmatic statements to be made regarding its effects. In all cases it produces diuresis, but only in four of the cases was any rise of blood-pressure observed, and in all of these there was marked arterio-sclerosis present, so that it is not certain whether the rise is to be attributed merely to the effect of the drug, especially as in the other three cases there was no rise recorded, although the tincture was steadily pushed to the most extreme limit of toleration. I have always regarded strophanthus as a safer drug than digitalis when given in small doses, say, 5 mins. thrice daily; but I think that when given in larger amounts it involves greater

(a) "Therapeutical Society's Transactions." London. 1906.

risks than is the case with digitalis which may be given in 15 mins. doses with absolute safety in many instances. It is certainly true that strophanthus is a much more powerful diuretic, even in small doses, than digitalis; and it should, therefore, always be employed when a diuretic effect is desired in cases of heart disease.

Squill, I found, in the three cases which I observed, varied very greatly in its effects. It is known that when squill is injected into the circulation in the case of animals it causes a much greater rise in arterial pressure than digitalis. My experience has been that in some cases the pressure rises slightly at one time, but remains constant at others. Of course the facts of its great rapidity of absorption and its somewhat transient effects may account for this. At all events in one of my cases I found no alteration in arterial pressure after the exhibition of 15 mins. of tincture scillæ every four hours for ten days. In another case the pressure, which was 150 mins. at the start, rose to 160 mins. at the third day, but fell again to 150 mins.; while in my third case the sphygmomanometer hardly ever gave the same record twice in succession. The patient, however, was a very nervous youth with marked mitral regurgitation, and the application of the instrument invariably excited him.

Caffeine is a drug whose effect on arterial pressure I have investigated in my own case. Three grains of the citrate produced no change. With 5 grains I observed at first a rise (?) which amounted to only 5 mins. This, however, might be almost discarded. Within a quarter of an hour the pressure, which was 120 mins. to start with, rose to 130 mins. and in half-an-hour to 135 mins. The headache from which I was suffering was definitely increased. Not until an hour and ten minutes after I had taken the drug did I find the pressure return to normal. On another occasion I took 10 grains. In ten minutes there was 15 mins. increase in the blood-pressure, and in half-an-hour 140 mins. was reached. Only in two hours afterwards did I obtain the normal reading. I experienced considerable inconvenience from copious diuresis. Caffeine is often recommended as a remedy in cases of migraine. I am confident that its use in such cases is really far from beneficial and actually aggravates the condition by raising the blood-pressure in the cerebrum.

It has been stated that strychnine is of little or no value as a direct heart stimulant. I am not prepared at present to argue for or against this statement, but I would remark that it is certainly a most valuable stimulant to the circulation in cases where the latter threatens to fail, as in pneumonia. Its effects on arterial pressure are very definite. I have carefully observed these in several cases, and have come to the conclusion that when the blood-pressure has fallen below the normal strychnine is the drug to administer. Within a very short time after its hypodermic administration a rise of as much as 40 mins. has been obtained. When given by the mouth the rise is never so rapid or so great but still it can be recorded. Nor is it necessary to administer large doses in order to produce a definite rise in the arterial pressure. This may be readily obtained by giving 5 mins. of the liquor strychnine hydrochloride by the mouth or by injecting 2 or 3 mins. hypodermically. I think the time has come when our knowledge

regarding the actions of drugs must be revised in accordance with definite clinical experience. It is high time that laboratory work were more largely supplemented by observations made at the bedside by workers trained in methods of clinical research. It is obviously impossible for anyone engaged in teaching and at the same time in practice as a physician to find time to carry out these observations extensively. They demand time which can often be but ill afforded. This work, however, appeals to hospital residents and those newly qualified who could easily carry out such investigations under the direction of their superiors. My candid belief is that the more we know of the real actions of drugs the more limited will be the number of those which we employ. Certainly the effect of drugs on the arterial pressure is a question of great importance, and if my results are accurate, it is undoubtedly time that much of the older teaching on the subject should be set aside. Meantime these brief observations may serve to stimulate the interest of others who have better opportunities for carrying out what is a very important and absolutely essential research.

A NOTE ON THE PREVENTION OF CANCER.

By J. FLETCHER LITTLE, M.B.CANTAB.,
M.R.C.P.LOND.,

Medical Officer of Health, Harrow-on-the-Hill.

MEDICAL observers are agreed that the chief predisposing causes of this disease are chronic irritation and injury. Therefore if the following rules were observed there should follow considerable diminution in the mortality from cancer, which in the Harrow district has caused more deaths than tuberculosis during the last five years.

RULES.

1. When warts, moles (especially dark-coloured) and other skin growths are exposed to constant irritation they should be immediately removed.

2. Workers who use tar or paraffin are especially liable to hard warty growths on the hands, forearms and other exposed parts of skin. Treatment should be sought early for such growths, as they may readily go on to cancer. Sweeps should take daily baths to remove the soot. Workers with X-rays should be effectually protected.

3. Avoid excessive smoking, as it predisposes to cancer of the lips, tongue, cheeks, etc. Inhaling cigarette smoke tends to cause cancer of the vocal cords.

4. Avoid irritation of the tongue and cheek by broken, jagged teeth, and of the lips by certain kinds of inferior clay pipes, which leads to cancer.

5. Avoid excessively hot food and drink, which induces cancer of the throat. Fluids and solids should not exceed 100 degrees Fahrenheit. Many people take food and drink at 120 to 150 degrees Fahrenheit.

5a. Avoid taking large quantities of iced drinks and ices, as digestion ceases when temperature of the stomach is reduced below the normal, which is 98 degrees Fahrenheit.

6. Masticate all food thoroughly, as food imperfectly chewed causes chronic irritation of the alimentary canal, involving the gullet, the entrance and outlet of the stomach, as well as that organ itself, and various parts of the large and small bowels, especially the termination of the former.

Cancer of the food tract spreads to the liver, gall bladder, pancreas, etc.

7. Take great care of the back teeth or grinders, and see that all of them are present and in perfect order. Dentists should be employed to make good any deficiencies. Money spent on the teeth will bring a greater return than any other investment.

8. Avoid bolting imperfectly masticated food. This bad habit can be cured by not drinking during a meal. Liquids may be drunk in small quantities at the end of a meal, or in larger quantities between meals.

9. Do not delay when cancer is suspected. Early recognition and prompt removal deprive cancer of its terrors. The mutual assistance of the public and the profession is essential to early diagnosis, and a grave responsibility rests on both. Thousands of lives of women suffering from cancer of the womb, and of the breast, could be saved by early diagnosis and operation.

9a. Avoid constipation. This is to be done by judicious diet and exercise, and, should these fail, by physical and medicinal treatment.

10. Avoid the use of alcoholic drinks, as they are a predisposing cause of cancer, and diminish the average prospects of survival by 30 per cent.

11. Circumcision should be performed in early life.

THE MATERIAL OBLIGATIONS OF SPIRITUALISM AND ALLIED PHENOMENA. (a)

By T. CLAYE SHAW, M.D., F.R.C.P., ETC.,

Emeritus Lecturer on Psychological Medicine, St. Bartholomew's Hospital, London.

MR. PRESIDENT AND GENTLEMEN,—In thanking you for the honour of your nomination to give the Harveian Lecture, I approach the subject with some trepidation, because I have no new laboratory facts to introduce. You are, I know, men with modern methods of precision *au bout des ongles*, whilst I am in daily contact with introspection and subjective assertion, with mere declarations which are often as emphatic as they are apt to be fallacious, and are only partly capable of that real demonstration of truth which we call experimental repetition with a determinate result. Though I am appealing to practical men, I recognise that I am at the same time addressing men of imagination, but with this difference from the ordinary mind-flights of the poet and the painter, that whilst the latter use their fancy to explain their facts, you preferably and more soundly establish a firm basis to rise from and then soar away in amazement at the wonders you have brought about. If then, like Icarus, the son of Dædalus, I fall to the ground from rashly attempting heights without the appropriate equipment, I must beg you to remember that the legend may have helped to the realisation of the modern conquest of the air by starting from below and then getting upwards. There are two kinds of students of mental science—those who start from below and are absorbed in the investigation of a very complex machine which, as yet, they have been only partially successful in unravelling, recognising that in its working or functioning there is something which they do not understand, and content to put aside as belonging to a different order; and there are those who start from above, who juggle with what they call the manifestations of mind and occupy themselves with ethereal disquisitions on imponderable essences. And the two groups of students laugh at each other, when in reality they ought to weep at the chasm which separates them and is at present insecurely bridged by unstable hypothesis only! The one sect, the Materialist, says that it is enough to know that there is a machine which acts in a certain way when it is in good order and in

other ways when it is impaired, within limits which are capable of demonstration; whilst the other, the Spiritualist, says "Bother your machine! It could not make itself nor equip itself with the functions which we see. It must have been created by a Superior Agency who endowed it with the functions which it presents, and who, for His own pleasure, left in it a little of His own power, called free-will, a very delicate balancing force, to enable it to regulate and keep in subjection the many destructive tendencies which enter into its composition." As a consequence of this intermediate conflict the quacks and fanatics and irregular expositors step in—as they always do when there is no responsible authoritative body with its own charter of monopoly to stop them. Hence the army of thought-readers, of crystal-gazers, of second-sight professors, of mediums and Christian Science exponents, who have a large following of persons prompted by curiosity to explore the unknown and re-inforced by the wish to learn what is the nature of an unknown land which they hope will yield a crop of possibilities and benefits beyond all present conception.

The belief in a supreme regulating power is universal in some shape or other, whatever be the race of people or whatever the time of their existence. In the more primitive races this idea took the form of a power or a god which had to be appeased by sacrifices of blood, because what I have elsewhere called this *Hæmathymia*, this idea of blood, was associated with all that is the most potent factor in bodily life, and therefore the most precious thing which could be offered. Even in times so recent as the Old Testament we find the proposed immolation by Abraham of his son and afterwards the rules as to the sacrifice of thousands of animals to appease the wrath of the Deity. In still later days the New Testament, whilst emphasising that without shedding of blood there is no remission of sins, forbids the sacrifices of the Old Testament, and it is still the upholder of emotion as the basis of action, but whereas the earliest people trundled their cars of Juggernaut owing to the emotion of Fear, the later made another emotion, Love, their corner-stone. There was no true Science in those days—even in our present times Science is incomplete, there are many regions into which it has to advance and disperse the enveloping darkness; but it is progressive, and the question is whether it will, in its turn, become the God who has been hitherto so ignorantly worshipped. It is probably in consequence of this apprehension that the spiritual school—the Church—has up to quite recently viewed Science askance, has looked upon it as an insidious enemy seeking to undermine "truths" which must be received by Faith, thus placing Speculation on a higher level than Fact; because so far it has not been possible in every instance to demonstrate in a scientific manner all the speculations which form their Belief. There is, however, a disposition on the part of some of the more liberal and better-educated exponents of theology to recognise that there is a chain of connection between spiritual and material processes, and that there need be no heresy in acknowledging this; moreover, they see that the one has to us no meaning without the other, and therefore there is cogent reason for accepting the dictum that the one is not more wonderful than the other and that each must be subject to laws, and, as they are inter-connected, probably to the same laws. Let me in proof of this present to you a curious analogy which struck me some time ago when thinking on this inter-connection. It is with no idea of irreverence, but with the full conviction that what I am about to say points to the unity of the Divine and the human nature that I draw attention to a very striking comparison between the science of Bacteriology and the fundamental basis of the Christian religion—to use the words of the Church, the incarnation of the Spirit of God with the man Christ. Categorically stated, it amounts to this, that as a vaccine is the material or essential factor of a disease similar to that which it is intended to cure, and as it is passed through an animated being before it is used for the human subject, so the evil and the fallen nature of man (weakness, temptation, passion and emotional stress) were

(a) The Harveian Lecture, read before the Harveian Society, on Thursday, March 28th, 1912.

passed through Christ, and thus used for the cure and salvation of morally diseased Humanity. Thus Christ became the anti-toxin of sin and moral infirmity. I have mentioned the analogy to several broad-thinking ecclesiastics and they have freely accepted it. Perhaps the most we can say of the theological trend of to-day is that it is in a state of *velleity*, one of imperfect or incomplete volition, not having made up its mind how far it can go. It seems impossible for the human mind to have a complete view of the abstract; the concrete is sure in some degree to obtrude, to thrust itself forward unsolicited. Thus we cannot think of Space without some form of delimitation attending it, of Time without a beginning or an end; and when we try to imagine Spiritualism or a spiritual body, or the so-called Astral body, or even the common ghost, we objectify it after the fashion of human resemblance. Man himself is said to be "the image of God," and therefore the supernatural in old, and even in modern theologies is represented by material images more or less distorted and moulded according to the functions they are supposed to possess. The idea of Heaven itself partakes more or less of this vicarious interpretation; according to some it is a place of gold and ivory thrones, of golden harps and instruments of music. You remember that the late R. L. Stevenson hoped it was not "an eternal tea-party with the guests ironed-out and immaculate." And I think that Charles Lamb must have embodied his idea of Hades when he wrote:

"Is it a party in a parlour,
Crammed just as they on earth are crammed?
Some sipping punch, some drinking tea,
But by their faces as you see
All silent and all damned."

When we talk of the Soul, or the Spirit, or of matter as consisting of the most infinitesimal electric Ions in a whirling motion we cannot escape presentations of a something with outlines of various kinds according to different trends of experience and education. Even Electricity and Light and Sound we think of as waves of *Æther* vibrating in different ways, and in our ignorance of what Life and Force are we view each as an invisible, imponderable, infinitesimal Agent—but still an Agent—whatever be the Force of which we are at the moment speaking we connect it with certain agents through which alone it is manifest to us, and this whether we speak of Magnetic, Electrical, Odic Force, or even of Life itself and Spirit—all these we presume to be different (though probably inter-related) because they have definite ways of shewing themselves. If these agents or expositions existed as mere forces we should not know nor even conceive them and, therefore, we are ready to acknowledge that there may yet be other forces, of which we have no conception because they have not yet envisaged the embodiments by which alone they can be made manifest to us. Why are people content to think without curiosity of speculation on the wind, which they cannot see? True, some nations have erected temples to the winds, but we have emancipated ourselves from any serious supplication to *Æolus* and *Boreas* and *Favonius*—why do they apply the forces of magnetism and electricity without bowing down in adoration to them or striving to understand their inner nature? Why do they contemplate light just as it is without concerning themselves with the awed regard of what it really is? Why, moreover, when the potentials of Soul and Spirit are spoken of, do they not treat them as they treat the equally mysterious forces of magnetism and electricity? Why, further, do they despise and repudiate the conclusions of scientists when these touch on what is held to be the particular work-ground of biblical oligarchy? Is it simply because soul and spirit investigations are entirely concerned with living matter whilst the other forces are more immediately apparent through the agency of inorganic conductive media? If so, it shows a want of appreciation of what is now known of the degree to which live matter responds to these very stimuli which are so complacently treated, while they forget that there is a considerable body of thinkers called *Hylozoists*

who maintain that there may be a low form of consciousness in inanimate matter. The fact is that, just as electricity and magnetism, the force of gravity, and so on, appear to have their exponents chiefly in inorganic matter, so does the Soul or Spirit especially select man, animal life, as its vicarious ally; but inasmuch as Life, Soul and Spirit are supposed to be of the essence of, if not indeed identical with, the creating God, it is held to be a profane and useless pursuit to pry into the nature of these "hidden mysteries," which are only to be dealt with by a select few nominated—as in the tabernacle of old—by themselves. However the forces of electricity and light arose, they are just as wonderful as any form of spirit-life, and as they all are but different manifestations of the same thing, whatever it is, there can be no more indubitable right to examine the conditions of any one of these sources of manifestation than there is of the others. Thus fortified, I propose to take the spiritual idea as it is commonly held, even if the difficulties appear to be insurmountable, and to see what are its *obligations*, what it ought to be if the present ideas of it are in any way correct.

We will begin with the obligations of the spectre or the ghost theory: If anyone says that he has seen a ghost, he means that he has seen an image with a certain amount of solidity of shape and colour both in features and dress, either moving about and speaking, or simply gesticulating in various ways, and then disappearing. This means that a spirit, which is a replica of a former object, can assume a solidity or can condense itself so as to be capable of exciting vision, and can then re-vapourise and disappear. If a spirit can do this, it must be capable of again becoming material, and if it is able to *move* and *speak* it must be living material, however attenuated its form may be. Inasmuch as it appears at one time in one guise and at another in a different one—but all as visitations relating to the same recognised individuals—it follows that there must be a spiritual form corresponding to every phase of actual life, and that the selection of a particular presentation must be a result of deliberate choice. Now the change from one form into another means that the spiritual condition must to some amount expend itself in assuming the material shape, the two cannot exist together in the same intensity as when they were separate and dissociated, so that the necessary assumption is that when the ghost of an individual appears the spirit of the individual is replaced by it. But if the spectre is clothed, how does this happen? Clothes, we know, are things of short duration, and in most instances, as in e.g., the Hampton Court Ghost Lady, they must have been torn up or have rotted into dust and been scattered years ago! Have the clothes then a spiritual life (it would seem that the *Hylozoists* would say so), or does the spirit of the lady possess the power of gathering together the scattered dust of courtly confections and re-inhabiting them, or out of the millions of phases of actual life which we have already hinted as one of the necessities of the spiritual hypothesis was one so favourite a habitation that it is especially selected for actual re-habilitation, though the materials for this have long since been destroyed? Take another instance, that of the re-vivification of a skeleton which is supposed to reappear with all the accompaniments of movement, and which is stated to be a return of the spirit of the original man. If it could be proved that when the spectral bones appeared the actual skeleton was not to be found where it was known to lie, and that on the disappearance of the visitation the remains were again in *loco quo ante*, there might be ground for the belief that a temporary resurrection had occurred, but such an alternation never has been proved. The postulate then comes to this, that for a spectre to be possible there must be a dynamic change of the immaterial into the material by which the former loses its separate individuality—the two cannot exist together in the same way: if the spectre is to appear the spirit disappears, because observation of life shows us that if there is an "Anima," it is never shown except through living matter. No one has ever

seen a spirit in any other dis-associated shape—what has been seen is a substance, just as, for comparison, the invisible steam in a boiler becomes the white vapour which we see after it has done its work. I am not saying there is no such thing as Spirit, but I do say that if there is it must have Laws and that it must conform to these Laws, one of which is that in manifesting itself it must lose in one direction what it takes on in another, and that as we have no knowledge of dead matter ever having been revived and made capable of responding to spiritual influence we have no justification in saying that such an occurrence ever happens, no more than we have to say that water has ever been known to run uphill, or the force of gravity to draw a stone up to the skies, or a piece of wood to contort itself under an electric current. Spiritual energy has to do with living matter, it has no correspondence or relation with what is dead. I am, of course, aware that this statement may be traversed, especially by the evangelical school, by what is vouchsafed to us in the Gospel of St. Luke, cap. 24, on the re-appearance of Christ after his martyrdom. Whatever views may be held on this event (which we must admit to be a true narration of what was testified to by many witnesses), we do at least find in it a clue to the metamorphic continuity of spirit and matter, by the transition of one into the other and the converse. That a dead person should reappear whilst his body is as yet incompletely changed, and that it should show signs of consciousness such as utterance of warnings, signs of expression and movement, etc., is impossible. Hence stories of spectral manifestations, of spirit-rapping, of spirit-séances and messages from the dead must be impostures. *They cannot be.* This conclusion does not deny the possibility of the influence of the combined Soul or Spirit and Body of one individual upon another *during life*, even at a distance, though I have never read or heard any convincing proof of it. If the telepathic hypothesis is that one spirit can communicate with another, there is nothing to be said except that we know nothing about such a condition of attenuated matter. If it means that a Force or Spirit can operate on living matter and cause it to communicate with other living matter at a distance, then I say that this communication must be of a vibratory nature using what we term the Ether, but we have no experience and no knowledge that living matter can act in this way except at comparatively short distances, and then only in a mechanical way, as by loud shouting. There is no other ground for this way of explaining such a phenomenon as is said to occur. If it is supposed that one individual, by a process of hard, concentrated thinking, can reveal what is in his mind to another living person without the intervention of something in the way of a material conductor, then I say that in the first place there is not an idea, or any set of ideas *per se*, anything of a material nature which can act upon a vibration medium, and, secondly, that if it is said that the idea (supposing it to be either abstract or material) can be carried by a spirit to another person whose nature is in harmony, then it must be assumed that the spirit is at the command of the material, whereas the whole of the spiritual hypothesis is that the spirit is the regulating and moving Power, and is not at the command of the material, though it may choose to work through it. In all these so-called demonstrations this power of inferior matter to *compel* the higher Spiritual Force which is said to have made it and to guide it, is surely a rock upon which the hypothesis is wrecked. "We may call spirits from the vasty deep, but will they come if we call them?" said Hotspur to Glendower. The same is seen in spirit *séances*—questions are asked of the unknown influence, and it may safely be said that no answer conveying knowledge has ever been returned as to future events. There is no future material available at the moment. Nor has anything been "revealed" as to what is going on *in the present*—nothing objective, nothing beyond what can be traced to the subjective condition of the material individual, showing that the material cannot control the spiritual, and that therefore there is no

ground for believing the claims of those who allege that they can obtain answers from a spiritual world. These claims are based upon the untenable theory that a lower form of matter can control that which made it and is ruled by it. That the Spiritualist's ideas are in all respects material, that his conceptions of what is the nature (even in his so-called spiritualised state) of the spiritual world are *essentially material*, and therefore subject to the laws governing matter, is easy to prove from what they say. Their fallacy is that they assume that a spirit is non-material, and yet they describe the nature and functions of this spirit in an absolutely material way, which is very like the logical process of *petitio principii*. If they said,

Spirit is an inconceivable Thing;

We hold communication with Spirits;

Therefore we hold communication with inconceivable Things

(which is a correct syllogism in form), we should see the absurdity of their position at once, for how can one hold communication with what cannot be conceived even to exist?—the middle term is wrong; it is a *petitio principii*—these people assume that they are conversing with a Spirit, which, according to the first term of the premisses, is an inconceivable (and according to their own allowance an immaterial) Thing, and yet all the time they *see* it, they *feel* it, they *hear* it, and they describe it as material, and in any other way than as material they have no knowledge, no conception of it.

In a book called "Theokosmia," published by Messrs. Kegan and Trübner, there is a detailed exposition of the Spirit-world, giving professedly a full account of the gradual entry into the sixth (or most highly elaborated) Sphere, the very Heaven, of the "double" of a certain William Norman Wilson. This biography is essentially a material view of what professes to be a non-material existence. Its visions are material, its agents are material, and the lessons it teaches are nothing but a repetition of the doctrinal theology of every-day experience. It begins by a definition of the "double," which is described as "simply a portion of the soul." The body of any person who has a double (thus implying that there are persons without souls) does not subject the entire soul, and the double is that section of it which is free. Where dwell the thoughts and desires of that portion of the soul under subjection (*i.e.*, mixed up with the body) there the double is drawn, and helps the other part to concentrate its thoughts; all of which means that a portion of soul which is left in the body needs help to concentrate itself upon itself, but there is no indication that a free soul is any way different from a tied soul. It is difficult to see how the former can help the latter without losing energy, in which case it must after a time lose its power and therefore its nature; and if the tied soul cannot dissociate itself from the body, how is it that the freed soul, which is essentially the same as the tied soul, succeeded in freeing itself? Why, when it has lost energy by trying to help the tied soul, does it not again become chained to and held in subjection by the body? The subject of these excursions into the various spheres of spiritual refinement then gives an account of the various agents who assisted him in his flights and questionings. These agents are women, assisted by a "stranger" who employs electricity to maintain the lessening combination of soul or Spirit with body material, as the distance from one lower sphere to a higher (and a delimited one, too) is reached. So that as the Spirit progresses it clearly loses power over the body and is obliged to be helped by an inferior agency, a sort of *re-lay*, through another force of a nature lower in quality than itself, for it is acknowledged that "the stranger is inferior and subordinate." All this looks very material! When in our ordinary mundane existence we use a horse to draw a load up a hill, and when, after a time, the animal through expenditure of energy, becomes weaker and cannot draw the load, we employ a "stranger," a man who has brought an electrical traction engine with him, to help to overcome the laws of gravity. This spiritual explorer (specially

"elected," to use his own phrase) finds his guides and conductors in three female beings whose appearance and methods are eminently material, and they are known to and converse with him under the not unfamiliar names of Minerva, Marian and Louisa, besides "the stranger" who is an electrical engineer—and whose special function is to keep up continuity of soul or spirit with what remains of the material body in its course towards death through gradual separation from the spiritual element (which is here called "Life")—for he explains that as he ascends higher and higher his body, which was left behind lying on the sofa, became more and more an inert bundle of flesh and clothes. The description of Minerva is that she consists of two blended parts, the Power which is evidenced by "brightness" and the figure which resembles what her body was, though now without material properties (another instance of *petitio principii*). The figures of the other spirits are more or less described in the same material way, and when our interest is wound up to the pitch of expecting the most important revelation, the result is—nothing; "questioning was not allowed to go further because the conversation was bordering upon subjects which man is forbidden to be made acquainted with." The whole story reads like a dream (which the writer owns to be a different state from spiritual conditions) and it is essentially the dream of a man strongly imbued with the teaching of accepted theologians; there is nothing in it which is not material, and the vaunted immaterial or spiritual information is nothing more than what one may hear in an every-day sermon.

(To be concluded in our next.)

PROPOSED PUBLIC DENTAL SERVICE.

By ROBERT R. RENTOUL, M.D.

WHEN, in 1889, I proposed that doctors should establish a Public Medical Service, I also suggested that it should not only supply efficient medical, surgical and maternity treatment and medicines to those of the public making limited incomes, but also reliable dental treatment. Such proposal has not, unfortunately, been yet taken up to any extent. In 1907 a Public Dental Service was established at Brighton. The fees are paid either in cash or by instalments, and they vary from 1s. to 2s. 6d. for extractions, with 8s. 6d. for gas; fillings from 2s. 6d. to 5s. each tooth; and artificial teeth from 5s. each to an inclusive charge of 50s. Some years ago I induced a society, to which I am medical officer, to appoint a dental surgeon. He has a fixed scale of charges for extractions, anæsthetic, fillings and mechanical work. The benefit members appreciate this system. This society has also a panel of chemists, who dispense our prescriptions at a 15 per cent. to 25 per cent. deduction on the usual prices. It includes those civil servants making up to £600 a year, the yearly rates of their incomes being arranged on a graduated scale of £100, £250, £400 and £600, these each paying yearly 8s. or 10s., 15s., 20s. and 50s. for unmarried members, with 1s. to 5s. per annum for working expenses, while the married pay 15s., 20s., 30s., 40s. and 100s. per annum. There is also a graduated scale of surgical fees, the latter from 30s. to 105s. It is a great pity doctors and dentists did not adopt my proposal of some twenty years ago. But, then, many hold that doctors and dentists have not an organising or constructive sense! I would suggest that the dentists at once establish a Public Dental Service. Before the National Insurance Act was finally passed, I pointed out that although there were medical, sanatorium, sickness, maternity and disablement benefits, no provision had been made for dental benefits. But if reference be made to Part 2 of Schedule 4 it will be found that "dental treatment" may be provided for as an "additional" benefit. This being so, it is necessary that dentists should at once establish public dental service in every local area, or combined area.

Dentists often complain that a great many people go

to the charitable dental hospitals for treatment. But if they will devote as much time to a constructive policy as they now do to growling, and agree to treat those with smaller incomes at fixed charges, then they would benefit themselves and the public. I find that at the dental hospital at Liverpool during 1911 no less than 33,534 patients obtained treatment, these paying £228 in contributions and £306 for fillings and plates. At this hospital, the following charges are made:—Application card 1d., crowns 7s. 6d. each, porcelain 5s. 6d., porcelain inlay 1s. 6d., gold per grain 6d., plastic 3d., universal charge 5s. The question of efficient dental treatment is of national importance. I have lately collected statistics from about two hundred school medical officers, and find that the condition of the children's teeth is deplorable, if not disgraceful. The majority seem to think that when the Creator laid it down that the young child should have twenty teeth, and the adult thirty-two, He made a very gross mistake. Many have only two, ten, or twelve teeth. Others have a mouthful of diseased teeth which resemble a malodorous cesspool. People do not seem to realise how injurious to health it must be when they inhale the bad odours given off by decaying teeth. How unpleasant and disgusting it is to be a bystander. If one were advised by a doctor to inhale constantly, day and night, such a smell, he would be labelled "mad." Take, again, the injury to the neighbouring organs. A loss of several teeth means that the food is bolted and unchewed, with this result, that work is put upon it that no stomach can perform. If the toothless human animal could, like the birds, swallow small pebbles which help to break up the food in his stomach, good would result. Again, it may be estimated that a number of rotting teeth will form about one teaspoonful of pus, or matter, daily. This is squeezed out by and mixed up with the food, and swallowed, with the result that the patient poisons himself or herself. Some time ago a doctor who had operated upon the stomachs of seven patients found that all these died with symptoms of blood-poisoning. This puzzled him, but eventually he found that all of them had rotting teeth; that they had swallowed the pus or matter, and that this had worked into the fresh wounds in the stomach, poisoning the patients. Since then he refuses to operate on persons until all their putrefying teeth have been put right.

It is now fairly well recognised that the pus from decaying teeth is absorbed in the mouth and throat, and so may give rise to enlarged tonsils, adenoids, tuberculosis, glands in the neck, discharging ears, acne of the face, and deafness. If one could extract all the diseased teeth in a patient's jaws, and then advise the patient to put these in his or her mouth daily for twelve hours, this would really be a practical but painful education as to the very insanitary condition of the mouth. That some great national movement must take place regarding the many millions of decomposing teeth carried about by English people is the opinion of those few pioneers of thought and action now working for this end. During 1910, of 45,671 persons wishing to join the British Army, 2,601 were rejected because of "loss, or decay" of many teeth. The Chief Medical Officer of the Board of Education, in his annual report for 1910, states that from 52 to 99 per cent. of children attending elementary schools have defective teeth. These children include only those between the ages of five and 16. How many below and above those ages are defective it is not difficult to estimate. This we do know, that the average man and woman will spend their money on anything whatsoever before they will expend it upon their teeth! The last annual report of the school medical officer of Liverpool displays a most disgusting and repulsive condition of affairs. Of the school children 16.54 per cent. only had sound teeth, 45.28 had one to three decayed teeth, 36.93 per cent. four to eleven decayed teeth, 1.25 twelve or more decayed.

It is difficult to adopt practical measures to stem this particular form of national degeneracy. If the toes and fingers of the population began to ulcerate

and decay, a Royal Commission would soon be appointed. Perhaps a few prosecutions of parents under Section 12 of the Children Act, 1908, would be of educational value, as under this Act parents may be heavily fined for neglecting medical aid for their children. One certain method by which dental aid can be obtained for four-fifths of our population is that which can be supplied through an efficient public dental service. Will the dentists fail in this public duty?

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

ABDOMINAL NEPHRECTOMY FOR TUBERCULOUS KIDNEY.—Mr. C. GORDON WATSON operated on a woman, aged 42, who had been admitted complaining of an abdominal swelling. On examination a large tumour was found occupying the right hypochondriac and lumbar regions. The surface was nodular, dull on percussion, and the swelling was somewhat movable on respiration. There was no hæmaturia or pyuria. An X-ray examination showed no stone. There was no rise of temperature, and no pain associated with the swelling.

Mr. Gordon Watson expressed the opinion that the swelling was renal, and probably malignant, and that it was in all probability inoperable. He proposed to explore by the abdominal route in order to make a diagnosis. If he found that the tumour was operable, he was confident that, from the size of it, it could only be removed per abdomen.

At the operation an incision was made in the right linea semilunaris, the rectus sheath was opened, and the rectus muscle retracted inwards; then the abdomen was opened, and the wound enlarged. The tumour was found to be renal, and proved to be extremely adherent to the surrounding parts. Its outer border was adherent to the abdominal wall, its inner border to the omentum, colon and stomach, and the upper pole to the liver. The ascending colon had been pushed inwards, so that there was no colon resonance in front of the tumour. The kidney was found to be elastic, and as there seemed to be some doubt as to the nature of the enlargement, it was punctured with a trocar and cannula, and some caseous material withdrawn, which, Mr. Watson pointed out, was strongly suggestive of tubercle. He then decided to attempt a nephrectomy, having first ascertained the existence of a normal-sized kidney on the other side. The hepatic flexure of the colon was densely adherent to the upper pole. During the separation of this adhesion, both the lumen of the colon was exposed and the kidney opened. These openings were closed with catgut, and the upper pole of the kidney was then separated from the liver. During this proceeding a severe venous hæmorrhage occurred, which was controlled by gauze plugs beneath the liver. Several adherent portions of the omentum were then tied off and divided. The lower pole was separated with some difficulty, being closely adherent to the lumbar muscles. The ureter was then sought for, ligatured and divided. The renal vessels could not be separately identified, but the pedicle was clamped and tied by degrees, and with considerable difficulty the kidney was eventually removed. Some attempt was made to repair the peritoneum of the posterior abdominal wall, and a counter incision was made through the loin, through which a large rubber tube was inserted. The abdominal wound was then closed, and a drainage tube inserted through the lower end. The operation lasted an hour, and the patient suffered a great deal from shock. During the latter part of the operation about a pint of saline was infused subcutaneously. The kidney proved to be tuberculous. The patient eventually made a very good recovery from the operation.

Mr. Watson stated that it was unusual to find so large a tuberculous kidney with such extensive

adhesions without there being either signs or symptoms of inflammatory mischief, such as irregular temperature, pyuria, or leucocytosis. It was unusual, he said, to find tuberculous infiltration extending from the kidney into the substance of the abdominal muscles, as in this case; in fact, the clinical picture and naked-eye appearances were those of malignant disease. He pointed out that it was fortunate he had punctured the kidney after exposing the swelling, as otherwise he would not have attempted the removal of so adherent a kidney had it been malignant, nor would such a removal have been justified. One of the great dangers associated with removal of large adherent kidneys, he considered, was hæmorrhage, due to tearing of the renal vein, or even in some cases of the vena cava. This, he thought, was far more likely to occur should the attempt be made from the lumbar region rather than through the abdomen. With regard to the large area left by the removal of the kidney, he remarked that it was important to cover this over, if possible, to avoid subsequent intestinal adhesions which might result in intestinal obstruction. He had covered this area partly by peritoneal suturing, partly by making use of the omentum. Lumbar drainage was considered essential, on account of the large area from which oozing might occur.

SPECIAL REPORTS.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE fourth annual meeting of the Oxford Ophthalmological Congress was held at Keble College, Oxford, on July 18th and 19th last, and, as usual, proved to be a very successful affair. There was a large attendance, and many of the visitors came from over-seas. Canada was represented by Dr. Hanford McKee, of Montreal. From the United States came Drs. W. B. Marple and J. A. Andrews (New York), Dr. Howard F. Hansell (Philadelphia), Dr. Miles Standish (Boston), Dr. Green (Dayton, Ohio), and Dr. W. Likley Simpson (Memphis, Te.). The Continent of Europe sent Drs. H. Coppez and Van Lint (Brussels), Dr. Brandes (Antwerp), Dr. R. Leibrecht (Hamburg), and Professor Straub (Amsterdam). The programme, a full one, kept the members fully occupied during the two days of the Congress. In the Department of Human Anatomy and Physiology belonging to the University of Oxford, addresses were delivered by Professor Straub, Dr. W. B. Marple, Dr. Hanford McKee, and Drs. Thomson Henderson (Nottingham) and S. E. Whitnall (Oxford). Following the custom of the Congress, the addresses, which were of commendable brevity, were followed by no discussion. The Professional Museum, also held in the Department of Physiology, included many exhibits of interest. Pathological specimens were demonstrated by Mr. Russ Wood and Mr. Sydney Stephenson. Ingenious optical appliances were shown by Dr. Ernest Maddox, Dr. J. Burden-Cooper, Mr. H. H. B. Cunningham, and others. Dr. A. J. Ballantyne had a set of coloured drawings illustrating many diseased conditions of the fundus oculi. The exhibit by Dr. H. S. Elworthy, of Ebbw Vale, deserves a word of special mention. It dealt mainly with geological specimens concerned with mines and mining, and included samples of house and anthracite coal, tin ore, various metals, and rock. Dr. Elworthy also demonstrated the "holophane lumeter," a new instrument for measuring illumination in mines; a set of colour tests for measuring colour in mines; and an apparatus for standardising colour tests. Another exhibit of interest was by Dr. T. Llewellyn, of Bargoed, namely a series of lantern slides dealing with miners' nystagmus. The anomalous cases of miners' nystagmus, brought by Dr. T. Harrison Butler, of Leamington, attracted no little interest, especially among those members not familiar with the conditions illustrated.

The *clou* of the Museum, however, lay in the 250 coloured drawings of mammalian and reptilian eyes

exhibited by the ophthalmic artist, Mr. A. W. Head. They disclosed many surprising variations of structure. An album garnished with photographs of Mr. Head at work on the eyes of the cobra di capello, the boa constrictor, the tiger cat, and many another fearsome animal attracted great attention and excited no little amusement. The Commercial Museum contained the latest things in the way of surgical instruments, optical appliances, lenses, microtomes, and so forth. The most interesting feature of this section was Gullstrand's demonstrating ophthalmoscope, whereby an image of the fundus oculi, of singularly pure quality, could be readily obtained even by an unskilled observer.

On the second day of the Congress a discussion, opened by Dr. T. Harrison Butler, on miners' nystagmus was held at the Oxford Eye Hospital. The discussion was notable on account of the number of gentlemen having a working knowledge of the subject who spoke. It was no mere arm-chair discussion. The following, among others, took part:—Dr. J. Court (Stavely), Dr. H. Tomlin, (Shirebrook), Dr. H. S. Elworthy, Mr. H. H. Folker, Dr. T. Llewellyn, Mr. S. McMurray, Dr. A. C. Norman, Mr. N. C. Kidley, Mr. J. Jameson Evans, Mr. Bernard Cridland, Mr. R. J. Coulter, and Mr. Stanley Riseley. As the outcome of the discussion, the following resolution was unanimously passed:—"That in the opinion of the Congress, the character of the illumination is the chief factor in the production of Miners' Nystagmus, and that a Departmental Committee should be appointed to make enquiries into, and to report upon, the exact conditions under which the disease occurs."

The official dinner of the Congress, presided over by the Warden of Keble College, was held on July 18th. Other social arrangements included a garden party at New College, and visits to the various colleges for which ancient Oxford is famed. The meeting must be written down as an unqualified success.

THE EIGHTIETH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, HELD AT LIVERPOOL, 1912.

FIFTH ARTICLE.

[FROM OUR SPECIAL REPRESENTATIVE.]

THE ANNUAL EXHIBITION—DRUGS, DISINFECTANTS, ETC.

THE practitioner who wishes to keep up to date cannot afford to neglect a thorough inspection of the newest products of the well-known drug houses. No one could have been disappointed this year in the display of the many new remedies that were on show. At the stand of the Bayer Co., Ltd., we were shown samples of a new local anæsthetic and antiseptic, known as "Cycloform," also "Sophol," a non-irritating organic silver compound for use in ophthalmic practice. The same firm were also exhibiting two preparations of iron, "Ferro-Sajodin," and "Irocase," for use in rickets, anæmia, and scrofulous conditions. Jeyes' Sanitary Compounds Co., Ltd., displayed to advantage their familiar and indispensable "Special Fluid Cyllin," in addition to many useful preparations of this well-known disinfectant. Messrs. Parke, Davis and Co. presented a large assortment of interesting products, including "Codrenine," a new local anæsthetic and ischæmic solution containing adrenalin and cocaine; "Palol," a tonic nutrient and restorative, containing the alcohol-soluble principles of cod-liver oil, minus its fatty glycerides, malt-extract, and glycerophosphates. A complete series of bacterial vaccines and serums was also exhibited. An ideal concentrated liquid magnesia was shown by the Charles H. Phillips Chemical Co., in addition to a phosphomuriate of quinine tonic, for use in derangements of the nervous and digestive systems. At the stall of Messrs. Savory and Moore we saw "Fructole," a new chemical food, containing iron, glycerophos-

phates, and red bone-marrow, with a fruit flavouring, and "Aphrodont," a Dental Foam, a capital antiseptic tooth-paste, possessing valuable germicide properties. Messrs. Zimmer and Co., Ltd. (represented by Messrs. Widenmann, Broicher and Co.) were showing a large number of high-class products, including "Aponal," a safe and effective hypnotic; "Eupyrin," a mild antipyretic for children and the aged; and "Lygosin-sodium," of use in the treatment of female gonorrhœa. Messrs. A. and M. Zimmermann exhibited an immense number of interesting preparations, which included "Tebeau" (Schering), a new immunising and curative remedy for tuberculosis; "Bioferrin" (Kalle), a blood-forming organic iron preparation; a selection of the organotherapeutic products of Prof. Dr. A. von Poehl, and "Bilitin" (Ludwig Wilhelm Gauz), for gall-stones. Messrs. Armour and Co., Ltd. exhibited "Eucapren," a local hæmostatic and analgesic. The Liverpool firms were represented by Messrs. Evans, Sons, Lescher and Webb, Ltd., Messrs. Clay and Abraham, Ltd., Symes and Co., Ltd., and R. Sumner and Co. "Kerol" disinfecting fluid was being shown by Messrs. Quibell Bros., Newark, while "Izal" was in evidence at the next stand. A striking exhibit of "Antiphlogistine" was to be seen at the stall of the Denver Chemical Manufacturing Co. Messrs. Reynolds and Branson, Ltd., of Leeds, presented many interesting and useful products, including a new and valuable preparation of ergot, known as "Ergothe." The well-known "Vasogen" series of preparations was shown by Messrs. E. T. Pearson and Co., Ltd. Among the excellent products to be seen at the stand of C. and J. Hewlett and Son, Ltd., were "Evapogens," a series of medicated skin lotions, and "Iodermiol," a non-staining and non-irritant preparation of iodine. "Iron Jelloids" were being shown by the Jelloid Co. The "Sanitas" Co., Ltd., were demonstrating the virtues of "Sanitas Fluid" and "Sanitas Oil." The Huxley's Pharmaceutical Products, etc., exhibited their well-known "Betul-Ol" and "Colchi-Sal," among other interesting preparations. At the stand of Messrs. Oppenheimer, Son, and Co., Ltd., were noticed "Collosols," of mercury and silver, and "Pulticine," a new antiseptic substitute for poultices. Messrs. Wyleys, Ltd., of Coventry, were showing some friction cakes—liniments in solid form, and "Ruscol," an organic compound of bismuth and birch-tar in ointment form. The Saccharin Corporation, Ltd., exhibited "Novocain," "Pergenol," and "Trivalin" (Overlach), a new morphia preparation and nerve tonic.

INSTRUMENTS AND APPLIANCES.

There was a particularly good display of every description of electro-therapeutic instruments and appliances, and the buzzing and sparkling of coils, interrupters, etc., made quite an agreeable accompaniment to the inspection of this section of the exhibition. Messrs. Newton and Wright, Ltd., were showing a new form of couch, complete with protective tube box for screen work and radiography from below, and fitted with an improved diaphragm compressor. The same firm also demonstrated a unique miniature X-ray set, adapted for carrying about. Messrs. Siemens Bros. and Co., Ltd., exhibited the "Oscillo-thermex," an outfit combining the apparatus necessary for diathermy, high-frequency treatment, and X-ray work. They also showed a series of radium applications of various sizes as well as radio-active materials and earths. At the stand of Messrs. Schall and Son we noticed a new high-frequency apparatus, the "Invictus," for use by medical men who do not possess, and who have no need for an X-ray installation. The firm's well-known "Pantostat," a universal apparatus for supplying current for various electro-medical purposes, was much in evidence. A new type of apparatus for giving the full body treatment, with smaller appliances for dealing with the limbs and parts of the body, was exhibited by the Dowling Radiant Heat Co., Ltd., possessing many advantages over other forms. The principal features of interest at the stand of W. Watson and Sons, Ltd., were various

improved forms of apparatus for X-ray work, including a modified form of tube box to the Ironside-Bruce Couch. The Cavendish Electrical Co., Ltd., were showing an apparatus, exhibited for the first time in public, for producing static currents from any X-ray coil, working with its own interrupter and switchboard, as usual. A collection of appliances utilised in ionic medication proved a most interesting exhibit. A neat and simple "Standard" set for X-ray work was shown by Harry W. Cox and Co., Ltd. An apparatus for producing absolutely pure ozone as an aid to ventilation was exhibited by Ozonair, Ltd., a unique modification of which was the form designed for the treatment of pyorrhœa alveolaris, chronic ulcers, etc. The well-known "Repello" and the Germ-Proof Clinical Thermometer were shown by Mr. G. H. Zeal. The Skeffington's Patent Recumbent Invalid Lifters were seen in active working, and their ease of manipulation and comfort appealed at once to all who have had the experience of lifting helpless patients. Some useful bedsteads and children's cots were shown by J. Nesbit-Evans and Co., of Birmingham. The Holborn Surgical Instrument Co., Ltd., had an interesting collection of instruments and appliances, among which we noticed the "Hedonal," and a "606" outfit. A series of incubators was shown by Chas. Hearson and Co., Ltd., suitable for every variety of bacteriological and pathological work. Anæsthetic apparatus and requisites for dentists were exhibited at the stand of Messrs. Claudius Ash, Sons and Co., Ltd. A large and comprehensive selection of instruments was shown by Messrs. Down Bros., Ltd., including many recent types and adaptations of earlier models. Messrs. Alexander and Fowler, Liverpool, were showing, among an interesting series of exhibits, some appliances and splints in a new alloy of aluminium, of the strength and hardness of mild steel, but only half the weight. Many different types of ophthalmoscopes and retinoscopes were shown by Messrs. Reiner and Keeler, Ltd.; Patent varus-boots and kidney belts and corsets were the special features of Messrs. Salt and Son's exhibit. Sir James Barr's apparatus for the treatment of serous effusions was among the instruments displayed by R. Sumner and Co., Liverpool. Messrs. Reynolds and Branson, Ltd., Leeds, showed an apparatus for oxygen and thorium inhalation. C. J. Hewlett and Son, Ltd., exhibited an improved lancet for quinsy, and an improved cervix cupper, among other new surgical instruments. Electric examination lamps, and the Hill-Herschel improved gastroscope were prominent amongst the exhibits of Messrs. Mayer and Meltzer. Various polygraphs and sphygmomanometers were shown at the stand of Messrs. Hawksley and Sons. John Weiss and Son, Ltd., exhibited a new surgeon's instrument-bag, with fitted trays, and many new models of ophthalmological and other instruments. The Scholl Manufacturing Co., Ltd., demonstrated the advantages of their patent arch supports for flat feet and other orthopædic appliances. At the stall of the Liverpool Lint Co. were specimens of "Vulnoplast," the newest and most complete dressing, with self-adhesive edges, as well as "Impermiettes," a substitute for ordinary rubber-coated sheetings. The merits of the Harcourt Chloroform Inhaler were demonstrated by Messrs. John J. Griffiths and Sons, Ltd. "Ronuk," Ltd., was much in evidence for polishes, stains and stoppings for preparing hard-wood floorings for polishing. Mr. C. A. Hoeffctke showed his appliances for joint diseases and fractures, including an apparatus for obtaining extension of the spine in various spinal diseases. An apparatus for rendering water radioactive was shown by Radium, Ltd.

MEDICAL BOOKS.

Many new and important medical works were on view, representing every branch of medical science. It is impossible to give a list of them all, or even of those which the practitioner who loves his library would fain add to his collection. We may mention a few, however. At the stand of Mr. H. K. Lewis were to be

seen the tenth edition of Carter's "Elements of Practical Medicine"; Binnie's "Manual of Operative Surgery," re-written in one volume; and the fifth edition of "Public Health Laboratory Work," by H. R. Kenwood. At the stall of W. B. Saunders Co. we noticed the three octavo volumes of "Practical Treatments," by 82 specialists, edited by Dr. J. H. Musser; Moynihan's "Duodenal Ulcer" (second edition), and the "Collected Papers of the Mayo Clinic" 1905-11. Rebman, Ltd., had a good display of their latest productions, including Mulzer's "Therapy of Syphilis," Hirschberg's "Treatment of Short Sight," and Guelpa's "Auto-intoxication and Disintoxication." Among the Oxford Medical Publications were Jamieson's "Care of the Skin in Health" Groves' and Brickdale's "Text Book for Nurses," and the fourth edition of Thomson and Miles' "Manual of Surgery." Messrs. John Wright and Sons, Ltd., were showing "An Index of Differential Diagnosis" of main symptoms, edited by Dr. Herbert French; the second reprint edition of Lejars' "Urgent Surgery," and Dr. Reginald Miller's "Medical Diseases of Children."

ANNUAL REPORT OF THE REGISTRAR-GENERAL FOR IRELAND.

ACCORDING to the annual report of the Registrar-General for 1911, the decrease in the population of Ireland for the period 1901-11 was only 1.7 per cent., as compared with a decrease of 5.2 per cent. in the preceding decennial period. In the middle of 1911 the estimated population was 3,374,584; the number of births for the year was 101,758, and the number of deaths 72,475, or an excess of births over deaths of 29,283, which should be the natural increase in the population of the country, but as the emigration amounted to 30,573 there was a loss in the population of 1,290. In the return the decrease compared with 1910 is 3,205. The estimate is, however, only for the middle of the year, while the other figures embrace the entire year. The deaths represent 16.6 per 1,000, while the loss by emigration is 7.0 per 1,000, or nearly half the death rate. Taken together, deaths and emigration amount to 23.6 per 1,000, while the birth-rate is but 23.3. The yearly average emigration rate for 1901-10 was 7.9 per 1,000, so that the loss last year was well below the average of the preceding decade. Practically only those in the prime of life emigrate. In the year under review 85.7 per cent. were between 15 and 35 years of age, and only 6.7 per cent. were 35 years or upwards.

The total marriages registered in 1911 numbered 23,473, representing a rate of 5.37 per 1,000, this rate was 0.32 above that for the previous year, and 0.21 above the average for the ten years 1901-1910. In the year 93.9 per cent. of the husbands and 98 per cent. of the wives wrote their names in the marriage registers, whereas in 1864 only 61 per cent. of the men and 50 per cent. of the women married were able to write their names.

In the provinces the highest marriage rate was in Ulster; in the county or county borough areas the highest rate was in the county borough of Belfast and the lowest in the county of Galway. Leinster had the highest birth rate, Munster being next, Ulster third, and Connaught last. The county or county borough areas which had the highest birth rate were in the following order:—Dublin Co. borough, Belfast Co. borough, Kerry, Limerick county and borough, Mayo, Antrim, Tipperary. It appears that of the children born in Ulster 3.7 per cent. were illegitimate; in Leinster the percentage was 2.9; in Munster 2.2, and in Connaught 0.7. The recorded death-rates for the four provinces were as follows:—Leinster, 18.5; Ulster, 16.8; Munster, 15.5; and Connaught, 14.0 per 1,000. The counties having the lowest mortality rates per 1,000 of the population were Kerry and Leitrim, each 12.8; Roscommon, 13.7; Galway, 13.8; Mayo, 14.0; and Tipperary North Riding, 14.4. The highest rates were as follows:—Dublin Co. borough, 24.1; Tyrone, 18.7; Armagh Co., 18.1; Kilkenny Co., 17.7;

Monaghan Co., 17.4; Wexford Co., 17.1; and Belfast Co. borough, 17.0.

There died from tuberculous disease 9,623, compared with 10,016 in 1910, a decrease of 393. Since the year 1904, in which the recorded death-rate from tuberculosis was 2.9 per 1,000, the rate had fallen to 2.2, which is the lowest rate yet presented by Ireland. The Registrar-General observes that:—"The decline in the mortality rate for tuberculosis in Ireland, which has commenced, cannot be dissociated from the foundation of the Women's National Health Association in 1907, and the personality of its founder, who continues to inspire its work." Of the twenty-two principal causes of death tuberculosis still heads the list in this country. It has been stated already that the death-rate from this disease was 2.2 per 1,000 in Ireland in 1911; the rate for Scotland was 1.8, and for England 1.4. It is not uninteresting to glance at the return of deaths from tuberculosis registered in each county in Ireland. All the west of the country from Donegal to Kerry has a low rate; also Louth, Meath, Monaghan, Cavan, Queen's Co., Tipperary, Kilkenny, and Carlow. The North-East corner of Ulster has a high rate; Dublin has an exceptionally bad record; the death-rate in Cork from the disease is rather high; Kildare, Wexford, Waterford, King's Co., and Westmeath are well above the average rate.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Aug. 17th, 1912.

ECZEMA OF THE FEMALE BREAST.

This form of eczema is never observed, according to Dr. Sabouraud, in the aged, but frequently in young girls. It is seated around the region of the nipple, existing generally on both sides, but always more intense on one or other and is of despairing tenacity. The nature of the eczema is an epidermitis, rose, moist, covered with yellow crusts that the under-jacent exudation detaches but incessantly renewed. Under ordinary treatment the affection improves and hopes are entertained of speedy cure, when suddenly it reappears and the whole treatment has to be gone over again.

When the eczema comes on during gestation, the breast gets enlarged, and pressure on the nipple forces out a drop of serosity.

Eczeema of scabies is easy to diagnose by its pustular form, while examination of the hands, elbows, etc., would clear up any doubt.

The treatment of this obstinate form of eczema is not however, very difficult. It is useless in the first place, to waste time on such anodynes as poultices, wet compresses, sprays, creams, etc. A strong solution of nitrate of silver (1-15) passed freely over the inflamed surface is the only effectual treatment. After this application, a piece of lint coated with the following ointment, followed by a slight compression by means of cotton wool and a bandage terminate the dressing:—

Oxide of zinc, 1 dr.

Vaseline, 5 drs.

Lanoline, 1 dr.

Rose water, 1 dr.

Eight days afterwards the skin will be black, but generally the eczema will be found to be cured. Isolated patches may remain which will require a little stronger solution (1-10).

Where the eczema is found on the face and neck as well as on the breast, it is not a case of eczema of the breast proper, but of a more or less generalised eruption. In such cases the nitrate of silver does not succeed as well as the tar ointment:—

Coal tar (washed), 1 dr.

Lanoline, 1 dr.

Vaseline, 6 drs.

As eczema is always epidermic and consequently never leaves behind a cicatrix, the patient may be

assured that the skin will return just as fine as before, and that fact will encourage her to accept without hesitation the treatment.

VARICOSE ULCERS.

The following method for treating varicose ulcers is much recommended by a surgeon as superior to all others. The leg is placed on an inclined plane (45°), the body keeping the horizontal position. After the limb is covered with a fine gauze or linen, ironed on both side to make it aseptic, a strong compression of the leg is made by an elastic band, beginning at the toes and reaching the knee. In this way ischæmia is obtained similar to that by Esmarch's band. As soon as the band has been rolled up the leg, it is removed, and the ulcer treated by the usual topics and a dressing applied; the patient wearing an elastic stocking can get up and walk. The elastic band, by compressing the dilated capillaries as well as the small veins and lymphatics, removes from the tissues the products of congestion, allowing thus fresh blood to circulate in the arteries. A better nutrition of the ulcer is the result and the healing more rapid. Varicose eczema can also be treated with advantage by the same method.

GERMANY.

Berlin, Aug. 17th, 1912.

At the meeting of the Charité Aerzte, Hr. Munter gave a short history of a case of

MISTAKEN DIAGNOSIS.

He showed to the meeting an impression taken from a man who had in the meantime died. It was a very typical case of mistake. The disease was really one of tuberculous ulcer of the lip that had over and over again been pronounced to be a hard chancre. The patient was a joiner, æt. 33, who had suffered from tuberculosis for twelve years. Last November he hurt his upper lip with a splinter of wood. This developed into a sore, which last January suddenly became swollen. He visited a hospital, where a diagnosis of hard chancre was arrived at. The Wassermann test was applied with a negative result; a search was made for spirochætae, also with a similar result. He was nevertheless sent into hospital for the purpose of undergoing a course of specific treatment. He left the hospital for external reasons and went to the Charité, where a diagnosis of tubercle was made, with the aid of the specialists in diseases of the skin. Numerous tubercle bacilli were found in the ulcer, also others in other parts of the mouth. If tubercle of the skin were divided into its different forms—the lupoid, the fungoid and the ulcerous, which Lesser had described as the flat ulcer with shallow, partly granular base, the miliary and the so-called tuberculide—the case before them was of the ulcerous variety. These ulcers often formed around the natural openings, especially around the anus, and the genitals in prostitutes. Apparently this tuberculous ulcer had had a different appearance. It did not now look like a hard chancre, but a soft ulcer as described by Lesser. Tuberculosis of the skin might also have the appearance of epithelioma. In that case they had flat ulcers with small white nodules on the inner side of the lips, yellowish plaques, which looked like plaques muqueuses, and flat ulcers on the tonsils. Like most of the cases the disease was secondary.

At the Gynæcologische Gesellschaft, Hr. Haendly showed a case in which the Röntgen rays had been applied to a case of

CARCINOMA OF THE CERVIX UTERI.

The case was one of inoperable cancer. The discharge was copious, bloody and foul-smelling. There was a distinct shrinking of the tumour under the treatment. Both hæmorrhage and foulness were less. During the treatment a rise of temperature took place with general symptoms. The mucous membrane of the vagina bore the rays better than the external skin. Lead-glass tubes were made use of, which were screwed on to the tube holder. The result was an encouragement to further trial in that direction.

Hr. Bumm had also used the rays in a case of

inoperable cancer of the cervix uteri with distinct benefit; he was of opinion that it was worth trying in cases too far gone for operative removal.

Hr. Gutzmann gave a short account of an

UNUSUAL CASE OF LABOUR.

A woman, æt. 33, was admitted into hospital on December 21st. Condition normal, pregnancy. There were no other signs of disease but one, and that a slight murmur at the mitral valve. The next day she had a headache, cough, and severe general symptoms. On the 24th there was hæmorrhage into the conjunctiva and bleeding from the nose. A day later spontaneous labour, which was normal. The symptoms otherwise continued very grave—high fever, parotitis, splenic tumour. Death in four weeks. The autopsy showed endocarditis, endarteritis, endometritis, etc. Bacteriologically nothing but pneumococci were found. The sepsis must have begun in the endocardium, and from there passed on to the uterus.

Hr. Franz discussed the question:

HOW CAN THE PERMANENT RESULTS OF OPERATION FOR CANCER OF THE UTERUS BE IMPROVED?

He believed that improvement lay above all things in improved *technique*. It was observable that with improved *technique* the results improved. That which was difficult to avoid was relapses from inoculation and infection. He did not use forceps for clamping the connective tissue by the side of the uterus, as he could not remove sufficiently radically by doing so. The deep lateral connective tissue must be dragged out. Tearing of the cervix must be avoided. At present it was not possible always to avoid inoculation. Recurrences should be removed, whilst Wertheim was of opinion that they should not be attacked. (Your correspondent would very strongly support Franz in this.) A timely discovery of recurrence could only be made by careful watching. Nodules might be nothing but connective tissue. The results, therefore, were to be improved by improved *technique*, great dexterity, gained by wide experience, watchful observation of cases, and more frequent operation in cases of relapse.

Hr. Mackenrodt thought that fat patients were more fitted for operation by the vaginal route than the abdominal. Age need not be considered. Operation had its limits when the disease had attacked the levator ani muscle. For preparation he recommended tr. iodi; he had given up the cautery, as it so often led to vesicovaginal fistula.

Hr. Bumm saw no advantage in widening the range of operability, and was in favour of disinfection of the vagina and of the clamp. He would not recommend operation for recurrences.

Hr. Franz, in reply, said he was opposed to the last opinion expressed. He had never denied that infection might be set up by a carcinoma.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

THE IRISH MILK SUPPLY.—The Irish Milk Supply Commission has been holding sittings in various parts of Ulster, and the evidence offered by medical and other witnesses is in many cases most interesting, as it throws light on the social condition of the people. The supply of milk seems to vary enormously in different localities; in many of the small towns it is abundant; it is the money to purchase it which seems lacking. It seems also that there is great ignorance among the people as to the value of milk as food; they prefer to spend their money on tea and whisky, and the poor children are brought up on baker's bread and these beverages. In the remote parts of Donegal where a farmer seldom has more than one cow, his family has to go without milk for many weeks in the year, and if potatoes fail at the same time, they live on tea and bread. It appears that the Congested Districts Board, which has done so much to improve the breed of cattle, has aimed at improving

the beef rather than the milk. In Londonderry the milk supply is abundant and of good quality, but, as in Belfast, much difficulty is experienced by the authorities in maintaining the quality of the buttermilk, which is constantly below par. There can be little doubt that the Inquiry is bound to do good.

COUNTY DOWN DISTRICT LUNATIC ASYLUM.—The annual report issued by Dr. M. J. Nolan, the Medical Superintendent of the Down District Lunatic Asylum, is always an interesting document, and coming as this does, a week after Dr. Graham's report on the Belfast District Asylum, it is doubly so, for both men travel beyond mere statistics, and give some results of their long experience in their general observations. While Dr. Graham puts his trust in the State, and better conditions of life brought about by a more advanced stage of evolution, Dr. Nolan emphasises his belief that while the State can do much, the individual can do more. "Prevention is largely in the hands of the State, but it is more immediately in the hands of individuals. For there can be no question but that the more practical application of Christian teaching would combat much of the stress that leads to insanity. The State doubtless may do much by philanthropic legislation to minimise the more distressful conditions of life—poverty, disease and ignorance. But even the most benevolent legislation may be rendered useless in individual cases where failure of the exercise of true Christian principles perverts the would-be blessing into a curse." As regards the year's work, Dr. Nolan reports 899 cases treated during the year—a daily average of 756. The recovery rate was 44.2, as compared with 36.5 for Ireland generally. The net average cost per patient was £22 3s. 6d., a reduction of 7s. 8d. on the previous year.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE NECESSITY FOR A NECROPSY IN EVERY CASE OF DEATH.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—In your last issue you kindly allowed me to add my testimony to that of Dr. McWalter, who, in his admirable paper in your previous issue under the above heading, had clearly demonstrated the uselessness of the Registrar-General's returns as at present compiled, when regarded from the point of view of medical or statistical science. I wrote particularly on the subject of infantile mortality, and although I felt that my statements were unimpeachable, I did not expect to find them corroborated from an authoritative source at the moment when they were appearing publicly in print. Since my letter was published, however, there has been issued the report of a Special Committee of the Royal Statistical Society to inquire into the systems of various countries for the registration of births (including stillborns) and deaths with reference to infantile mortality. It is stated that the scope of the inquiry was extended considerably beyond that originally suggested, and the report covers practically the whole system of registration and the calculation of vital statistics. It discusses the history of registration, the practice of registration in general, still-births, and statistical methods. Information has been collected from many sources within the British Empire, from European nations, the United States, and South American Republics. The answers dealing with the efficiency of registration convey, with few exceptions, opinions that registration is very fairly complete. The registration of still-births is not required by law in the United Kingdom, in many of our colonies, and in many foreign states. It seems that no Legislature has up to the present enacted any definition of still-birth, and the only guidance afforded to those required to declare and inscribe such births in places in which their registration is compulsory is that afforded by regulations made by the statistical offices.

It is pointed out that at the present time the principal function of vital statistics is the examination of the causes of unnecessary and preventable wastage of life and sickness. Vital statistics may, in effect, be regarded as taking the place of laboratory experiments in social physiology and pathology. The Committee insists that if such views be accepted as correctly representing the functions of statistics, it is evident that reliable conclusions cannot be obtained unless the basic data are reliable and accurate, and the methods of calculation used by different inquirers uniform, or at least strictly comparable. These latter utterances precisely express the contentions set forth by Dr. McWalter and supported by myself. Let us hope they may find a speedy acceptance by our responsible Government Departments.—I am, Sir, yours truly,

STATISTICIAN.

Birmingham, August 16th.

EXERCISE AND TRAINING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the *Daily Mail* of to-day (August 16), there is an article of much interest to most university men, entitled "A Wrong View of Amateur Sport." Those who consider the question of exercise and training from a medical point of view, and have some practical knowledge of the absolute necessity of studying this question physiologically and anatomically if they wish to arrive at sound conclusions, will not agree with Mr. W. Beach Thomas, "how old members of a university crew or those who have coached them can hold such a theory is not easily understood."

The simple question that most university men consider when they go in for boating or any other kind of exercise is really whether they are helped or not by it in the prime object of university life, that is in the steady promotion of their knowledge of those subjects of study to which they are devoted. Our best men at the universities in classics and mathematics have generally been eager athletes, for the simple reason that they found how much depends on "mens sana in corpore sano," and that constant steady exercise is of immense value when reading and working up for such exams as the Triposes at Cambridge or the Schools at Oxford. Exercise is one thing, and Training is another. To make the former impossible without the latter is just what "old members of a university" object to, and the reason why they "argue that the athlete who trains hard under any tutorship and specialises in any particular way does somehow soil and weaken his sportsmanship by taking this trouble," is really because the mind is so much diverted from proper work and taken up by training, that disappointments come, and sad reflections. As many of our profession are interested in the character and tone of university life and can undoubtedly influence the views that are entertained at our universities on such questions as Exercise and Training, if we only give some thought and attention to them, we may do well to do so when we see so much uncertainty prevailing between the old members of university crews, and such men as "the ex-president of the Oxford University Athletic Club."

I am, Sir, yours truly,
EXERCISE AND TRAINING.

OBITUARY.

PROFESSOR J. J. CHARLES.

We regret to announce the death of Professor J. J. Charles, which event occurred at Portrush on August 10th. His death removes what was for many years a familiar figure and a striking personality to past medical students of Queen's College, Cork. Born in 1843 at Cookstown, he obtained the M.D. degree with honours in the Queen's University of Ireland in the year 1865, and a few years later the M.A. degree in connection with which he was awarded two gold medals. After this Arts distinction, he was appointed Demon-

strator of Anatomy in Queen's College, Belfast, which post he held for a period of over six years. In 1875 he succeeded the late Dr. Corbett in the Chair of Anatomy and Physiology in Queen's College, Cork. He was the third occupant of this Chair since the foundation of the College, and for a period of over thirty years he discharged its onerous duties with a keen sense of his responsibilities, with marked dignity, extraordinary attention to detail, and genuine solicitude for his pupils' progress—all qualities that were eminently characteristic of the man.

MR. C. E. HUTT, OF TOTTENHAM.

We regret to announce the death of Mr. Charles Edward Hutt, of Tottenham, which took place last week, after a brief illness, at his residence, 626, High Road, at the age of 47. The deceased, who studied at St. Bartholomew's Hospital, qualified as L.R.C.P. Lond., and M.R.C.S. Eng., in 1888. He came to Tottenham some sixteen years ago, when he succeeded to the practice of Dr. Wunderlich. Pains-taking and conscientious in all his work, Mr. Hutt soon acquired a high reputation among the inhabitants of the district, as well as his professional colleagues, by whom he was greatly respected. He was formerly resident medical officer to the Hertford General Infirmary, and he was at one time surgical registrar to the Prince of Wales's General Hospital. He was also chairman of the Tottenham Division of the British Medical Association. His genial presence will be sorely missed at the gatherings of the Tottenham Medical Club, with which he was connected. Mr. Hutt was formerly an indefatigable worker in the interests of the North-East London Clinical Society, of which he was the first honorary secretary, being appointed to that office upon the foundation of the society in 1900. His sterling qualities and earnest work earned for him the post of president, after five years of laborious secretarial duties unremittingly performed. Only those who have served in a similar capacity in the case of a newly-formed society know what self-sacrifice is needed in order to make the thing "go" well, and this personal service Mr. Hutt freely and willingly gave. He had been the victim of cardiac trouble for some few years past, but this had seemed to improve of late. A severe anginal attack, however, seized him on the night of the 13th inst., to which he succumbed in spite of every medical aid. Widespread sympathy is felt with his widow and her young family in their bereavement.

DR. HENRY YATE PITTS. LIVERPOOL.

We deeply regret to announce the death of Dr. Henry Yate Pitts, which took place on Sunday, the 11th inst., at his residence, Victoria Road, Tue Brook, Liverpool. Dr. Pitts, who at the time of his death was in his 64th year, had been in failing health for some time. For very many years he was Medical Officer to the Liverpool Seaman's Orphanage, where the writer has no hesitation in saying that his presence was always like a gleam of sunshine to old and young. He was, after saying so much, naturally very popular with the children, as they, as well as all others with whom he was brought into contact, could not fail to see that any attentions his position required him to give, were always whole-hearted, and never given grudgingly. For many years also, each Christmas Day as it came round found him at the Orphanage, helping to assist in serving the little ones and doing his all to make the day a happy one for them.

Not only by those associated with him in that noble Institution, but by all brought into contact with him in daily life, will he be held in grateful remembrance. He was an ornament to his profession, which demands from its members that they shall be bright, true hearted, sympathising, ever ready to give of themselves for the good of their fellow creatures.

The deceased was born in Liverpool, studied mostly in his native city, was a member of the Royal College of Surgeons of England, and Licentiate of the Royal College of Physicians of London, and spent most of his life in practice in a suburb of Liverpool.

His funeral took place on the 14th inst. at Anfield Cemetery. Amongst other mourners who followed his remains to the grave were the following fellow members of the profession:—Professor Rushton Parker, Alderman Dr. Thomas Clarke, J.P., Dr. Percy Edwards, Dr. Benjamin Price, J.P., Dr. W. Blackledge, and Dr. J. P. Hall.

REVIEWS OF BOOKS.

WALLIS'S SURGERY OF THE RECTUM. (a)

FOR no very good reason diseases of the rectum have received scant attention by the general practitioner; and yet they are extremely important from the patients' point of view. We, therefore, welcome this manual, although we cannot but deplore the sad circumstance that the talented author died before this work was completed. The volume deals with all those affections of the rectum and anus commonly encountered in general practice. In the chapter on the symptoms of rectal disease some valuable remarks are made which will prove of great value to those who bear them in mind. The various forms of colitis are next considered, and a chapter is devoted to venereal affections of the rectum and anus. In the chapter dealing with anal fissure the author gives it as his opinion that dilatation of the sphincter is not always an essential preliminary to operation on this region. Very interesting and instructive are the author's remarks on pruritus ani. Examination of a large number of cases in his practice revealed the presence in over 90 per cent. of a small ulcer just within the anal margin, and always below the internal sphincter. A condition, which Sir Frederick Wallis terms ano-rectal ulceration, is referred to. This is an ulcerative state of the mucous membrane of that part of the bowel which lies between the anus and the internal sphincter. It is often the starting point of many of the ordinary rectal ailments.

Some very useful hints are given on the diagnosis and treatment of rectal and peri-rectal abscesses and fistulæ. The chapter on hæmorrhoids supplies the reader with a vast amount of original advice on the management of this extremely troublesome and painful affection. There are also special chapters on prolapse and neoplasms of the rectum, together with an account of the methods of excising the rectum and of performing colostomy. The concluding chapter on rectal diseases in children makes a suitable ending to a book whose practical teaching on diseases of the rectum we believe has no equal in the English language. The practitioner who takes the trouble to study and to carry out the author's advice will find in the gratitude of his patients more than recompense for the trouble he has taken to make himself acquainted with diseases of this region.

HERRINGHAM ON KIDNEY DISEASES. (b)

WITHIN recent years a great deal of original work has been done in connection with diseases of the kidney. It is, therefore, fitting that a volume on this subject should be included in the series of "Oxford Medical Publications." Dr. Herringham has given us a thoroughly up-to-date account of these diseases, which contains a vast amount of original thought and suggestion. While not neglecting to refer to the work of others in the same field, the author has for the most part stated his own personal opinions. Some of his sentences really savour of golden rules. Take, for example, the following specimens: "I have known

complete anuria rapidly relieved by leeches"; "Acute nephritis is not a common disease"; "Diffuse nephritis can produce hypertrophy of the heart and arterial sclerosis": We have been struck, in reading the pages of this interesting and stimulating volume, with their freshness of expression and statement. At times the author may appear to be very dogmatic, but in every case the evidence on which his statements are based warrants him in adopting such an authoritative attitude.

Dr. Williamson's contributions on renal diseases in pregnancy are extremely valuable. His remarks on pyelitis are of special interest, although we cannot altogether endorse some of them. He divides the cases into six distinct groups all of which we consider are quite definite and well recognised in practice. His statement, however, that the urine in such cases, as a rule, has no offensive odour we are inclined to question. The advice given regarding the treatment of pyelitis is sound and practical, and we are pleased to note that he counsels against prescribing urotropine or helmitol in tablet form. Personally Dr. Williamson always uses autogenous vaccines in such cases, given every third day in increasing doses until 50 million bacilli is reached.

This monograph on diseases of the kidney is a most valuable contribution to medical literature. It contains all that the general practitioner is likely to require in the way of information as to the diagnosis, prognosis and treatment of these diseases; and we can accordingly recommend it as in every respect a most convenient and practical work of reference.

THE THERAPY OF SYPHILIS. (a)

As Professor Uhlenhuth remarks in his preface to this book, the work of the Imperial Health Bureau paved the way for the improvement in the treatment of syphilis and directly promoted it by the discovery thereof of the *spirochata pallida*. It is natural, therefore, that Dr. Mulzer's little work should consist of a eulogy of arseno-therapy, accordingly we find eleven pages devoted to the influence of the results of syphilitic research upon the former mercurial treatment of the disease, while the rest of the book is taken up with a full account of the different arsenical preparations which have been tried and discarded in favour of the now famous dioxidiamidoarsenobenzol, or "606," the virtues of which are extolled, though in the last section the author admits that the principle of *sterilisatio magna* of Ehrlich has not been realised. He concludes that the practitioner should employ arseno-benzol in cases which are refractory to mercurial and iodine therapy, or which have been little influenced by these drugs. The contra-indications for the use of the new remedy are plainly set forth, and the advisability of employing mercury in conjunction with it is laid down. A comprehensive bibliography is given at the end, and there is a very full index. In our opinion, this book is a helpful guide to the modern treatment of syphilis.

TUBERCULIN IN TUBERCULOSIS. (b)

THIS book is mainly a vindication of the work and theory of Koch, after nearly fifteen years of careful and laborious observations on the part of the author who firmly believes that he is in the position to prove the truth of the following propositions as laid down by Koch;—(1) *Tuberculin is an invaluable and indispensable agent in the diagnosis of early tuberculosis, especially pulmonary tuberculosis*; (2) *the early stage of pulmonary tuberculosis can be cured with certainty by means of tuberculin*. Dr. Camac Wilkinson is known to hold somewhat advanced views with regard to the use of tuberculin, but he is not afraid to speak

(a) "Surgery of the Rectum, for Practitioners." By Sir Frederick Wallis, M.B., B.C. Cantab., F.R.C.S., Surgeon to Charing Cross Hospital, St. Mark's Hospital, and the Grosvenor Hospital for Women and Children. London: Henry Frowde and Hodder and Stoughton. 1912. Price 15s. net.

(b) "Kidney Diseases." By W. P. Herringham, M.D., F.R.C.P., Physician to St. Bartholomew's Hospital, etc., etc. With chapters on Renal Diseases in Pregnancy, by Herbert Williamson, M.D., F.R.C.P., Assistant Physician-Accoucheur to St. Bartholomew's Hospital, etc., etc. London: Henry Frowde and Hodder and Stoughton. 1912. Price 15s. net.

(a) "The Therapy of Syphilis: Its Development and Present Position." By Dr. Paul Mulzer, Berlin, with a Preface by Professor P. Uhlenhuth, M.D., P.C. Translated by A. Newbold. Pp. xv. and 247. London: Rebman, Ltd. 1912.

(b) "Tuberculin in the Diagnosis and Treatment of Tuberculosis." Weber-Parkes Essay, 1909, with additions." By W. Camac Wilkinson, B.A.Syd., M.D.Lond., F.R.C.P. Sup. roy. 8vo., pp. 492. London: James Nisbet and Co., Ltd. 1912.

out against the sceptical attitude which has been, perhaps unfortunately, adopted by many of the heads of the medical profession concerning the utility of this remedy in consumption. The tone is somewhat too controversial, but the author has the strength of his own convictions, and, what is more, these are backed up by actual clinical experience with the administration of tuberculin.

The first four sections of the book deal with "the greatest problem in medical science" as met with in the laboratory, in man, and for the physician. Since 1891, Dr. Wilkinson has treated more than 120 patients in the first stage of consumption, and not one of these has progressed to the second stage. With such a powerful remedy in their hands, the author believes that the medical men of to-day "have the opportunity to perceptibly reduce the death rate from tuberculosis two or three years hence." The limitations and shortcomings of sanatorium treatment as investigated by Weicker are confirmed by the author who states that if he had obtained such results (relapses, etc.) in his practice he would have been almost in despair. A large number of case-records and charts are given. The rest of the book is occupied with the *technique* of tuberculin injections, and the *rôle* of the tuberculin dispensary in combating tuberculosis among the poor. We have no hesitation in saying that Dr. Wilkinson's book is one to be carefully read and pondered over by all who are brought into contact with the consumptive.

SANDERS' MODERN METHODS IN NURSING. (a)

This is a volume of nearly 900 pages giving information not only on matters connected with nursing proper but also on bandages and splints, drugs and their doses, poisons and their antidotes, bacteriology, diets and dieting. The great fault which we have to find with this book is that it attempts too much. Thus we cannot see why a nurse should be taught methods of staining for bacteria or of making cultures. This is no part, or should be no part of her work. In these days there is far too much glib talk on the part of nurses about matters which only concern the properly trained practitioner. The nurse will do well to stick to her own peculiar function, namely the nursing of the patient. We regret, therefore, that we cannot give our unqualified approval to this book which, if intended for students and medical men, should have been written by a qualified man, but as it is only intended for nurses contains information on matters absolutely foreign to a nurse's work as that is usually understood. We therefore consider some of these plates, such as that of sphygmograms, as absolutely superfluous. The value of the book would certainly be increased were its size considerably reduced.

DISEASES OF THE EYE. (b)

ALL ophthalmic surgeons who are engaged in instructing students will welcome the appearance of a second edition of Mr. Stephen Mayou's "Diseases of the Eye." Taken all round, it is one of the most useful students' books on the subject. The general form of these manuals, of which it forms one, is excellent; the price is low, which is a great consideration to the student; and while no important subject is omitted, the text is not overloaded with a mass of detail which deals with non-essentials and confuses the student.

The plain illustrations, many of them from original photographs, are very helpful, though the coloured plates are not up to the standard of the rest of the book. It would, we think, be better if one really first-

rate coloured plate of the normal fundus were substituted for the eight rather primitive coloured illustrations now included. An important feature of the book is the full and clear account given of the more common eye affections, such as the general practitioner is called upon to treat. Conjunctivitis, trachoma, phlyctenular ophthalmia, and keratitis are all excellently described. A few statements might be criticised, such as that on p. 41, that in myopia the full correction with glasses should be ordered for distance in all cases; on p. 111, that patients who are the subjects of interstitial keratitis have suffered from congenital syphilis; and on p. 140, that in sympathetic iridocyclitis there is always keratitis punctata in the exciting eye. Such statements seem to us too sweeping and need some modification. But these are small blots on an excellent little book.

LITERARY NOTES.

MR. H. K. LEWIS announces for early publication new editions of "Mind and its Disorders," by Dr. W. H. B. Stoddart, of the Bethlem Royal Hospital; "Clinical Bacteriology and Hæmatology for Practitioners," by Dr. W. d'Este Emery, and "Materia Medica and Pharmacy for Medical Students," by Mr. R. R. Bennett, Pharmacist to University College Hospital. The same firm has in hand a new edition (the sixth) of Dr. Lewis Jones' "Medical Electricity." This will contain several new illustrations, and will be brought thoroughly up to date. A new book on Ionisation is in preparation by the same author, and will be issued at an early date. Mention may be made of new editions just issued of three well-known books:—"The Diseases of Women," by Dr. Lewers; "The Elements of Practical Medicine," by Dr. Carter, of Birmingham; and the fifteenth edition of "The Extra Pharmacopœia," by Drs. Martindale and Westcott, this edition being considerably enlarged, and the matter arranged in two volumes, for convenience of reference.

* * *

WE have received from Messrs. Bale, Sons and Danielsson, Ltd., a copy of a lecture by Mr. George Thomson, L.D.S., entitled "Sleep and Digestion." The lecture seems to have been delivered to a lay audience, and is now printed "with the earnest desire to disseminate common-sense views concerning health." The views expressed are common-sense, but the form of expression is a mixture of common-place and rhetoric which is unpleasant to read. The tract is published at the extravagant price of one shilling.

* * *

THE following new books are announced for early publication by Messrs. J. and A. Churchill:—"The Malformations and Congenital Diseases of the Fœtus." By Prof. Dr. R. Birnbaum, Chief Physician to the University Clinic for Women at Gottingen. Translated and annotated by Dr. G. Blacker, Obstetric Physician, University College Hospital. "Digestion and Metabolism." The Physiological and Pathological Chemistry of Nutrition. By Alonzo E. Taylor, M.D., Rush Professor of Physiological Chemistry, University of Pennsylvania, Philadelphia. "The Evolution of the Vertebrates and Their Kin." By Wm. Patten, Ph.D., Professor of Zoology, Dartmouth College. "Meat Hygiene, with Special Consideration of Ante-mortem and Post-mortem Inspection of Food-Producing Animals." By Prof. Richard Edelmann, Ph.D., of Dresden. Translated by John R. Mohler, A.M., V.M.D., and Adolph Eichhorn, D.V.S.

NEW PREPARATIONS.

"VAPOROLE" CHLOROFORM AND ETHYL IODIDE COMPOUND.

WE have received specimens of a new product issued by Burroughs Wellcome and Co., known as "Vaporole" Chloroform and Ethyl Iodide Compound,

(a) "Modern Methods in Nursing." By Georgina J. Sanders, formerly Assistant Matron at Addenbrooke's Hospital, Cambridge, etc., etc. With 228 illustrations. Philadelphia and London: W. B. Saunders Company. 1912. Price 12s. 6d net.

(b) "Diseases of the Eye." By M. Stephen Mayou, F.R.C.S., Surgeon, Central London Ophthalmic Hospital, &c. Second Edition, with 124 illustrations and eight coloured plates. Oxford Medical Manuals. London: Henry Frowde and Hodder and Stoughton.

which is intended for use by inhalation. It consists of a combination of chloroform, ethyl iodide and menthol, put up in hermetically-sealed capsules of delicate glass, and is issued in boxes of six. Each capsule is surrounded with absorbent material enclosed in a silken sac, so that when the product is to be used it is only necessary to crush the capsule and inhale the contents. "Vapörole" Chloroform and Ethyl Compound is recommended for all forms of laryngeal spasm, as, for example, in the dyspnoea of bronchitic asthma, in whooping cough and in œdematous laryngitis.

"WELLCOME" BRAND STREPTOCOCCUS VACCINE, DENTAL.

The treatment of pyorrhœa alveolaris by means of bacterial vaccines is a measure which of late has been employed somewhat extensively, and has met with a considerable degree of success. In the majority of cases of pyorrhœa it is found that the predominant organisms are streptococci. Messrs. Burroughs Wellcome and Co. have therefore issued, for use in this condition, the "Wellcome" Brand Streptococcus Vaccine, Dental, which contains several strains of streptococci obtained from cases of pyorrhœa alveolaris and septic conditions of the teeth and gums. It is a carefully prepared vaccine, produced under expert bacteriological control, and is issued, in hermetically-sealed 1 c.c. phials, in two dilutions, containing respectively 10 million and 50 million organisms. The dose of this vaccine is 5 million organisms, gradually increased to 50 million, and it may be given at intervals of seven to ten days.

MEDICAL NEWS IN BRIEF.

The Ophthalmological Section of the Royal Society of Medicine.

THE inaugural meeting of the newly-formed Section of Ophthalmology of the Royal Society of Medicine will be held on Wednesday, October 23rd, at 8.30 p.m. All registered medical practitioners are eligible as members of this Section. The Council of the Society has resolved to offer special terms to new members of this Section who also become Fellows of the Society. These terms can be obtained on application to the Secretary of the Society. Only those whose applications for either Fellowship or Membership have been received on or before October 5th and have been accepted by the Councils of the Section and of the Society will be qualified to take part in the inaugural meeting.

The National Insurance Advisory Committee.

TWENTY-SEVEN medical practitioners have resigned from the National Insurance Advisory Committee in accordance with the decision reached at the representative meeting of the British Medical Association. These include all the thirteen nominated by the Association to serve on the Committee, whose names are as follows: Dr. John Adams, Glasgow; Dr. R. M. Beaton, London; Dr. T. M. Carter, Bristol; Dr. J. S. Darling, Lurgan; Dr. S. Hodgson, Salford; Dr. J. A. Macdonald, Taunton; Dr. J. Munro Moir, Inverness; Mr. James Neal, Birmingham; Dr. E. O. Price, Bangor; Mr. D. F. Todd, Sunderland; Mr. E. B. Turner, London; Mr. T. Jenner Verrall, Bath; Dr. A. H. Williams, Harrow.

The resignation of those medical members nominated by the Government are as follows: Dr. G. R. Livingston, Dumfries; Dr. H. A. Latimer, Swansea; Sir Frederick Eve, London; Dr. John D. Lloyd, Chirk; Dr. J. W. Mulligan, Abersychan, Monmouthshire; Dr. J. Edgar P. Davies, Llanelly; Miss M. H. F. Ivens, M.B., Liverpool; Dr. P. T. O'Sullivan, Cork; Mr. W. Courtney Milward, Cardiff; Dr. E. J. Maclean, Cardiff; Dr. R. McKenzie Johnston, Edinburgh; Dr. D. Elliot Dickson, Fife; Dr. Anne M. Watson, Aberdeen; Dr. Lauriston E. Shaw, London.

The British Medical Association issued a statement last week replying to the resolution of the minority (14 in number) in order "to remove any suspicion that there is an official revolt in its ranks. The publication of the announcement that 14 members have refused will naturally lead some people who are not familiar with the position to assume that the medical members of the Advisory Committee are not prepared to act in accordance with the policy of the Association. Now, this is not the case, and it ought to be made clear to the public that every member nominated by the British Medical Association to serve on the Advisory Committee has already actually resigned. And in addition to these gentlemen, of whom there are 13, other 14 have resigned, making 27 in all."

The names of those who have not resigned are as follows: Dr. Addison, M.P.; Sir Clifford Allbutt, Dr. Clement Belcher, Mr. C. J. Bond, Sir John Collie, Mr. Adam Hamilton, Mr. M. St. L. Harford, Mr. Herbert Jones, Dr. Arthur Latham, Dr. H. H. Mills, Sir Shirley Murphy, Dr. George Reid, Dr. John Robertson, and Professor Sims Woodhead.

Ptomaine Poisoning on a Cable Ship.

AN outbreak of ptomaine poisoning from the consumption of tinned food occurred last week on the Eastern Telegraph Company's cable ship "John Pender," the captain, 18 officers, engineers, and members of the crew being attacked. Fortunately, when symptoms of acute gastro-enteritis developed, the captain and certain of the officers, having a knowledge of first-aid, were able to deal with the trouble to a certain extent, and this undoubtedly helped the sufferers. Dr. F. M. Williams, the port medical officer of Plymouth, and Mr. F. W. Weale, port sanitary inspector, visited the ship, and all the victims are now making satisfactory progress.

The Anthrax Investigation Board.

A MEETING of the Anthrax Investigation Board was held last week at the offices of the Bradford Chamber of Commerce, Mr. John E. Fawcett presiding. Dr. Eurich reported that since the last meeting of the Board on May 3rd four cases of anthrax had occurred, two in Bradford and two at Halifax. All were of the external variety, and all the patients recovered. In each case anti-anthrax serum had been injected. During the same period 264 samples of wool and hair had been tested for anthrax, with the result that anthrax spores were found in twenty-one instances. Experiments with disinfectants were being carried on, but were not complete. It was reported that representations had been made to the exporters of alpaca from Chili and Peru as to the desirability of taking precautions with a view to the risk of anthrax being reduced to a minimum. These representations had been well received, the senders undertaking to do all they could to assist in the direction indicated.

Hospitals Association's Conference.

THE British Hospitals Association will hold its annual conference in Birmingham on September 19th and 20th. It is expected that between 150 and 200 delegates will attend. A reception will be held at the Council House by the Lord Mayor on the opening day, and visits will be paid by the delegates to several hospitals in Birmingham and the district. Papers have been promised by Sir William Collins, M.P., M.D., and Mr. J. Danvers Power, by Mr. E. S. Kemp on "The Training of Almoners," by Dr. Nathan Raw on "The Insurance Act," and by Dr. Josiah Oldfield on "The Site and Size of a Hospital in Relation to its Efficiency."

University of Oxford.

At a Congregation held on August 8th the following degrees were conferred:—

D.M.—J. S. C. Douglas, Christ Church; P. H. C. Fowell, St. John's.

B.M.—D. P. McDonald, Oriol; P. L. Gibson, Trinity.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES on LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

MR. ALAN JACOB (Redditch).—The hospital ship *Maine* is as completely equipped as any naval hospital on shore. She has four main wards, in addition to a ward for infectious diseases, an operating theatre, and an X-ray room. Her war accommodation is 180. She is one of the Royal Fleet Auxiliary vessels, owned by the Admiralty, and she is under the command of Capt. Malcolm Tarver.

M.D. BAUX (London, N.).—Mountain sickness is not wholly the result of atmospheric conditions, its production being also influenced by the state of the nervous and digestive systems. Even such factors as chill and snow glare are included by such experienced climbers as Dr. A. M. Kellas.

WEAVERS' COUGH.

IN reply to a question the other day in the House of Commons, Mr. McKenna stated that he had received a report from the factory inspector upon the cases of certain weavers in a Burnley factory who were attacked by an unusual cough which affected their breathing. The ventilation in the shed in question was good. Expert opinion was that the outbreak was due to some mouldy sago in the "size" used in dressing the warps, causing mildew in the shed. The mill was closed and thoroughly disinfected, and measures were taken to prevent the development of mildew, the warps being damped with a solution of carbolic acid, with the result that a decided improvement had occurred.

DR. R. E. (Exminster).—Communication and enclosure received with thanks.

DR. F. H. J. (Darlington).—MS. duly received which has been marked for early insertion.

THE FISH SUPPLY OF LONDON.

THE clerk of the Fishmongers' Company reports that last month 19,181 tons of fish arrived at Billingsgate Market. Of that quantity 13,581 tons came by land and 5,600 tons by water. The Company's officials seized and destroyed 305 tons as unfit for human food. The principal seizures were of haddocks (97 tons), whiting (90 tons), plaice (25 tons), skate (24 tons), shrimps (14 tons), catfish (10 tons), periwinkles (seven tons), and whelks (six tons).

"ANTHROPOLOGIST" (Stafford).—It has been shown quite recently that the candidates for conscription in Denmark have increased $1\frac{1}{2}$ inches in average height during the past fifty or sixty years. A similar increase has also been noted in Norway, Sweden and Holland.

MR. P. R. (Bridgetown).—The presence of small quantities of manganese in animal tissues is a known scientific fact. In addition, minute traces of boron have been found by MM. Gabriel Bertrand and H. Agulhan, amounting to about one milligramme for seven kilogrammes of muscle.

Appointments.

DUFF, DONALD, F.R.C.S.Edin., F.R.F.P.S.Glasg., Assistant Surgeon to the Glasgow Royal Infirmary.

HUGHES, F. M., M.R.C.S., L.R.C.P., Assistant House Surgeon to the Poplar Hospital for Accidents.

JOHNSON, H. E., M.B., Ch.B.Edin., Medical Officer for the Callington District of the Liskeard Board of Guardians.

MESSITER, CYRIL C., L.M.S.S.A.Lond., Junior House Surgeon and Anaesthetist to the Croydon General Hospital.
VISING, C. WILFRED, M.D., B.S.Lond., M.R.C.P., D.P.H., Assistant Physician to the Leeds General Infirmary.
YULE, GEORGE PRATT, M.D.Edin., Medical Officer of Health of the County of Fife.

Vacancies.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary commencing at £160, with board, etc. Applications to Medical Superintendent.

St. Bartholomew's Hospital, Rochester.—Resident House Physician. Salary £110 per annum, with board, residence, and laundry. Applications to Charles Speyer, Secretary.

West Berks United Districts.—Medical Officer of Health. Salary £530 per annum, with an allowance of £330 per annum for travelling, office, and other expenses. Full particulars and forms of application of Bromley Challenor, The Guildhall, Abingdon.

Children's Hospital, Temple Street, Dublin.—Assistant Physician. Applications to Hon. Secretary.

Salop Infirmary, Shrewsbury.—House Surgeon. Salary £150 per annum, with board, washing, etc. N.B.—Ladies not eligible. Applications to Joseph Jenks, Secretary.

Portsmouth Borough Asylum.—Assistant Medical Officer.—Salary £150, with annual increments of £10 to £200, with board, lodging, etc. Applications to the Medical Superintendent on or before August 31st, 1912.

Govan District Asylum, Crookston, near Paisley.—Second Assistant Medical Officer. Salary begins at £150 per annum, with board, laundry, etc. Applications to the Medical Superintendent as soon as possible.

Queen Mary's Hospital for Children, Carshalton, Surrey (under the Metropolitan Asylums Board).—Assistant Medical Officers (three vacancies). Salary £150 per annum, rising £10 annually to £180, with board, washing, etc. Forms of Application of the Clerk to the Board, Embankment, London, E.C.

Devonshire Hospital, Buxton.—Assistant House Physician. Salary £100 per annum, with board (excepting stimulants), and laundry. Applications to be sent in at once.

West Riding of Yorkshire.—Tuberculosis Officer to assist the County Medical Officer in matters arising out of the administration of the National Insurance Act, 1911, in respect of Sanatorium Benefit. Salary £500 per annum. Further particulars will be furnished on application to F. A. Darwin, County Hall, Wakefield.

Somerset County Council.—Tuberculosis Medical Officer. Candidates must have held hospital appointments and be specially experienced in the diagnosis and treatment of tuberculosis and in the use of tuberculin. Salary £500 per annum. Applications must be sent to G. I. Simey, Sidney House, Boulevard, Weston-super-Mare.

Wilts County Council.—Tuberculosis Officer, who will have charge of the Tuberculosis Dispensary and Branches. Salary £500 per annum. Applications must be made on forms to be supplied. Apply to R. W. Merriman, County Offices, Trowbridge.

Births.

HERRICK.—On July 26th, 1912, at Kasauli, India, the wife of Lieut. R. de S. B. Herrick, I.M.S., of a son.

KATE.—On Aug. 11th, at Eaglestone, Strathpeffer, the wife of Henry Wynyard Kaye, M.D., Oxon., of a son.

MAIDLOW.—On Aug. 15th, at Ilminster, Somerset, the wife of William H. Maidlow, M.D., of a son.

Marriages.

BAXTER—EVERITT.—On Aug. 14th, 1912, at St. Andrew's, Wells Street, Staff.—Surgeon Charles T. Baxter, Royal Navy, youngest son of the late Alexander B. Baxter and Mrs. Baxter, of 430 Camden Road, N., to Margaret Louise, only daughter of Mr. and Mrs. Frank Everitt, late of 1 Dunsford Place, Bath.

TUNNICLIFFE—PHILO.—On Aug. 10th, at Holy Trinity, Marylebone, Francis Whittaker Tunnicliffe, of 129, Harley Street, and The Littens, Hampstead, Norris, Berks, to Minnie Gertrude, daughter of William J. Philo, of Dovercourt, Essex.

Deaths.

DOBBYN.—On Aug. 12th, at Walmer, very suddenly, John Stephen Dobbyn, M.D., F.R.C.S., of Streatham, late Deputy Inspector-General, R.N. (retired), aged 73.

HAIQ-BROWN.—On Aug. 10th, at St. Leonard's-on-Sea, Hopo Margaret, the wife of Clarence William Haig-Brown, M.D., Charterhouse, Godalming.

HALLOWES.—On Aug. 15th, at Ulverstone, Tasmania, Herbert Chaworth Hallowes, M.D., second son of the late Reverend Brabazon Hallowes, of Glapwell Hall, Chesterfield, in his 56th year.

HUTT.—On Aug. 13th, suddenly, at High Road, Tottenham, Charles Edward Hutt, M.R.C.S., L.R.C.P., aged 47 years.

MOFFAT.—On Aug. 10th, at Viewforth, St. James's, Cape Colony, South Africa, Hilda, the beloved wife of Dr. Robert Unwin Moffat, C.M.G., and youngest daughter of the late James and Helen Vavasseur, of Knockholt, Kent.

SHEPHERD.—On Aug. 12th, at 50 Kedleston Road, Derby, H. D. Shepherd, M.B., F.R.C.S.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 28, 1912.

No. 9.

NOTES AND COMMENTS.

A Wet August and the Public Health. THE pitiless rains which have marred the pleasure of so many holiday-makers during the present month, and have spelt consternation and even ruin to agriculturists, have not been wholly disadvantageous. From all quarters we learn that the high infantile mortality usually attributable to the epidemic diarrhoea prevalent during periods of drought and heat has been conspicuous by its absence. The amount of dust, laden with death-dealing germs, has been also practically negligible, neither has there been anything like the number of flies about to fall into the domestic milk-jug or to upset journalistic equanimity. Those sensations of lassitude and of "wanting a holiday" are soon dispelled when the thermometer cannot be induced to rise much over 60 degrees and the atmosphere is saturated with moisture. With distrust of the barometer begotten of past experience of its vagaries arises a feeling of secret joy that we are still in the old place and doing the same old things. What does it signify if we suffer a few more twinges of neuralgia or of rheumatism? Have we not the assurance of vital statistics that the effects of the diminishing birth-rate have been, to a certain extent, counteracted during the August of 1912 by lessening the customary seasonal massacre of the innocents? Such is Nature's great law of compensation.

The Passing of General Booth. By the death last week of the veteran leader of that unique organisation known as the Salvation Army, one of the most notable personalities of the present age has been removed from our midst. The movement initiated in 1865 by the Rev. William Booth, D.C.L. Oxon., to give him his official, but less homely, title, though primarily religious in its aims and objects, was also deeply concerned with the physical betterment of the "submerged tenth," towards the reclamation of which class of society its energies were, from the first, specially directed. That this champion of the outcast and degraded had a keen, practical insight into the methods of social reform is seen by the success of the multifarious schemes outlined in his famous pamphlet, "In Darkest England, and the Way Out," which appeared in 1890. In spite of the fiercest opposition experienced by the founder of the Salvation Army in its early days, he lived to see many, if not all, of the institutions that he devised for the relief of the suffering poor in a prosperous and flourishing condition. What is more, the truly imperial and international character of his work is universally acknowledged, not only by the evangelist, but also by the humanitarian and the statesman in all quarters of the globe. The establishment of shelters for the homeless, food depôts for the

starving, day nurseries for destitute children, and homes for the reception of drunkards, are only a few of the philanthropic schemes inaugurated by General Booth that have had a directly beneficial effect upon the public health.

The Title "Doctor" and Secret Remedies. A GOOD deal of work remains before the Select Committee upon Patent Medicines and Secret Remedies and Appliances can furnish a comprehensive report of the subject. Among the host of chicaneries by which the trade is maintained it may be fervently hoped that some witness will point out the abuse of the title of "Doctor" whereby the proprietors of nostrums deck their wares with the semblance of scientific authority. The Dr. Turner Company, of Great Portland Street, London, furnishes a case in point. It appears that Dr. Turner is a real personage, but the *Journal of the American Medical Association* denies that he holds any licence to practise medicine. A long list of secret remedies, some of them redolent of blatant quackery, could be detailed, in which a medical title appears in the description. In one or two cases the name of some illustrious deceased medical man has been profaned by the advertisement of some pill or potion claiming to cure a host of maladies. In all the long range of callous disregard for the decencies of life there is hardly one that for mean and cynical cunning can compare with this offence against the reputation of the dead. Of a somewhat similar nature is the quotation from the books of medical writers, living or dead, in the advertisements of claims that are from a scientific point of view no less monstrous than misleading. We venture to express a hope that the Committee will deal with these and other abuses tersely and thoroughly. It is curious that the General Medical Council should not long ago have used their influence with the legislature to put an end to the unauthorised advertisement of medical titles, real or fictitious, by the proprietors of nostrums and patent medicines.

Out-Patients and Fees. THE report of the King Edward's Hospital Fund Committee, briefly stated, is that only a few well-to-do people, able to pay ordinary medical fees, take advantage of the out-patient departments of hospitals. Before accepting that conclusion, we should require a full statement of the way in which evidence as to facts had been collected and sifted. It is hard to

imagine a case in which it would be more difficult to get pertinent and trustworthy evidence than on that of alleged hospital abuse. It is to the interest of hospital authorities to make light of the whole matter, and, obviously; it is unlikely that any well-to-do persons, even if caught in the act, will admit that they have abused the charity; nor can one readily see how their good faith is to be tested. On the other hand, more or less evidence leaks out from time to time and comes into the possession of the honorary surgeons or physicians, especially in the special hospitals where small fees are payable by patients who can afford them. An amusing instance of this kind of abuse was brought to our notice some time ago. A patient had been under treatment and had been in the habit of paying a small sum at each visit. Later, for some reason or other, he consulted a Harley Street specialist, whose fees for a course of vaccine treatment and injections of salvarsan amounted to a good round sum, which was paid without hesitation. The specialist paid this hospital patient a visit at his own house, a large abode furnished in sumptuous fashion with a bedroom suite that must have cost 50 or 60 guineas at the least. The King Edward Fund report on the other hand says there is in out-patient rooms a large class of people quite able to pay fees higher than the average small medical fees. What practical step does the Fund suggest in order to deal with this class? Are we to be taken back to the old principle of paying patients which has always been favoured by the King Edward and Metropolitan Hospital Sunday Funds?

LEADING ARTICLES.

SEASIDE RESORTS AND HEALTH.

THE annual summer exodus to the seaside naturally brings to the professional mind the sanitary aspects of the seaside resorts which his patients, and haply he himself also, may elect to patronise. From time to time, rumours of a disquieting nature reach the world through the medical or lay journals with regard to this or that sanitary defect in more or less fashionable and popular watering places. Outbreaks of enteric fever occur from time to time, usually through some fault in the water supply. Many of our readers will be able to recall the case of a large seaside town on the south coast which has never regained its prosperity after an experience of this kind. In spite of such warnings the water supply of certain resorts is still notoriously bad, and it would be possible to mention an important town depending upon summer visitors for a substantial share of its prosperity where the water supply of a considerable part of the central district is derived from ancient wells. Then, again, the house and general drainage system of many seaside towns is, to say the least of it, unsatisfactory from the point of view even of a low modern sanitary standard. Towns on the seaboard are in many instances necessarily built upon a low

level, and the main drainage is discharged upon the shore in the intervals between high tide. Owing to imperfect sewer ventilation a common result is that twice in the twenty-four hours there is a strong backward pressure of sewer-gas which, in scores of well-known seaside places we have visited, has been rendered patently manifest to the senses in the house lavatories. Indeed, were a systematic investigation to be conducted into the drainage and the water-supplies of our chief seaside towns results would probably be of a more or less sensational nature. It is surprising, indeed, that local authorities should acquiesce in a short-sighted policy which admits of lax and low standards in sanitary matters. As a matter of fact, the expenditure in such places on fore-shore construction and maintenance is often large and the inhabitants are saddled with heavy rates. That fact, although it partly excuses, does not justify the apathy of municipal sanitary administration, which is part and parcel of the existing system, which places local government in the hands of a handful of persons whose interests are often directly opposed to sanitary reforms, and against whose tacit resistance the power of the medical officer of health, however zealous and efficient he may be, becomes practically a dead letter. How otherwise could one account for the absence of any machinery for isolation and disinfection in one of the largest and best known of the watering-places in the West of England. In this case we believe that the energetic protests of a local physician resulted a few years ago in the addition of this primary essential to the health defences of the district. Some towns are specially favoured by unqualified medical practice as in the case of a leading Sussex resort in which a branch of the notorious Viavi remedies has been conducted for several years, and its advertisements exhibited on the public tramcars. In short, there appears to be an extraordinary lack of business management on the part of the local authorities of British watering-places due, apparently, to some peculiar trait in the national character. The result is seen in the numbers of our countrymen and countrywomen who throng the Continental spas and pleasure resorts. After all, the British watering-place is in the main of entirely modern growth, and we may hope without any undue stretch of the imagination that one day it will attain a standard of administration worthy of the best teachings of modern sanitary science. It may be safely assumed that in no other way is any particular health resort likely to be placed on a permanent basis of prosperity. The average seaside watering-place of to-day is infinitely better in every way, not less from the social than the sanitary standpoint, than that of half a century ago, so far as the visitor is concerned. In many of these

places, however, there is still room for improvement. The chief directions in which such expansion is likely to take place lie probably in the adoption of the most advanced standards of public health administration and the removal of a number of regulations that are hardly in touch with latter-day tendencies, many of which seem framed to discourage rather than to encourage the subsequent return of summer visitors. From the public health point of view the sanitary supervision of seaside towns is of sufficient national importance to merit specially close attention from the Local Government Board.

CURRENT TOPICS.

Overpopulation.

IN these latter days when there is so much discussion on Eugenics—writ large and in capital letters—and on National Insurance—similarly emphasised; when this man proposes drastic measures of dealing with the unfit, warranted, in his opinion, to produce a perfect race in record time, and that man imagines the robbing of Peter for the payment of Paul a panacea for impoverished humanity, it is wise to reflect on the fundamental principles underlying modern social conditions. Careful retrospection would often prevent us from instituting elaborate processes of dealing with effects whilst we ignore causes, or, on the other hand, from wasting our resources in attacking an impregnable fact fundamental in our being, whilst we might be better employed in rightly directing its applications. Regarding the economic history of mankind we are confronted with the fact that with the increase in food amongst civilised peoples there is a corresponding increase of population, and when the lean years arrive there is the inevitable local starvation and annihilation of a certain proportion of the people. When famine rages in India or China it is to be doubted whether the rest of the world could afford bread to feed the starving multitudes, not because of lack of money or inclination, but from lack of food. In fact, a certain percentage of every society is in constant want of proper nutriment. Were even every available acre of the earth under cultivation, in due proportion there would be more individuals dependent on the crops thereof, and always that percentage of the inefficient few, who could not obtain sufficient sustenance. The army of prosperous workmen has always the inevitable accompaniment of needy camp-followers. As in Germany to-day, immense commercial prosperity is burdened by huge numbers of unemployed, who "actually slaughter horses and dogs for food to sustain life." A suggestive paper in the *New York Medical Record* of August 10th points out that America, which for years furnished an outlet for the excess of European populations, is gradually presenting the same conditions that obtain in the parent countries. Social adjustments and economic settlements can avail little as long as men persist in reproducing beyond the resources of the soil. Let the morally and mentally dead bury their dead. The fit will survive.

Mortality Among Coal Miners.

THE Blue Book issued by the Chief Inspector of Mines on Saturday last contains the mortality statistics of coal miners during last year. It seems evident that if the deaths from accident could be eliminated, the lives of miners would be practically as "good" as those of average men in other trades. The number of lives lost last year, although marking a slight reduction over the record of the previous year, is still high. The total number of persons employed in and about the coal mines was 1,067,213, and there were 1,265 fatal accidents. This marks a decrease of 510 in the number of deaths compared with 1910; but in the higher total there are included 480 deaths attributable to the Whitehaven and Hulton disasters. The total number of non-fatal accidents during 1911 which disabled for more than seven days was 166,153, involving injury to 166,616 persons. This is an increase of 7,574 in the number of the injured when compared with the preceding twelve months. The death-rate of the underground workers in the coal mines was 1.29 per 1,000 persons employed, as against 1.91 in 1910; and the death-rate of the surface-workers was .73 per 1,000 employed, as against .76 in the previous year. The death-rate of the underground and surface workers as a whole was 1.19, as against 1.69 in 1910.

DR. ENID WALTERS, M.D., B.Sc., has been temporarily appointed School Medical Officer to the Bromley Education Committee.

DR. JOHN J. DENNEHY, M.B., B.S., N.U.I., has been appointed Superintendent Tuberculosis Medical Officer for the County of Waterford.

CAPT. J. S. PASCOE, R.A.M.C., has been selected for appointment as Specialist in Midwifery and Diseases of Women and Children to the Woolwich District.

DR. J. ELSDALE MOLSON, of Goring Hall, near Worthing, has been adopted as prospective Unionist candidate for the Gainsborough Division of Lincolnshire.

DR. ROBERT W. MURPHY, M.D., B.Ch., B.A.O., D.P.H.Dub., has been appointed Assistant Medical Inspector of Schools to No. 1 District of the North Riding, Yorkshire.

DR. ALISTER T. MACKENZIE has been appointed Administrative Medical Officer and Principal of the College of Hygiene at Dunfermline, under the Carnegie Dunfermline Trust.

MR. REGINALD STATHAM, M.R.C.S., L.S.A., of The Hall, Cheddar, Somerset, was recently the recipient of an engraved silver casket containing a sum of money as a mark of esteem and respect from his many friends and patients upon the occasion of the celebration of his silver wedding.

DR. THEODORE LEIGHTON PENNELL, M.D., F.R.C.S., of Bannu, on the North-West Frontier of India, medical missionary under the Church Missionary Society, who died on March 23rd, aged 45, left estate valued at £25,202 gross, with net personality £25,160.

MR. JOHN JEFFREY, F.R.C.S., of Jedburgh, Roxburghshire, has been appointed by the Secretary of State for the Home Department to be one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of Berwick, Roxburgh, and Selkirk, and to be attached more particularly to the County of Roxburgh, in place of Dr. W. Jeffrey, deceased.

better than the societies gave them before the Act." Another extract is in the form of an anonymous letter to the *Standard*, headed, "The Lunacy Acts: A Strange Case." In this what amounts to a charge of conspiracy wrongly to obtain paltry fees is made against members of the profession. "The Lunacy Acts endanger the liberty and destroy the lives of the poor and enrich the pockets of some medical men who are willing to take advantage of the fees they can so easily earn." This grave charge is supported by the narrative of a case which, we venture to affirm, would not bear investigation. If true it would have been necessary merely to state the facts properly authenticated, without the addition of vile imputations. The sole point our correspondent wishes to emphasise is, however, that the more the confidence in the medical profession is shaken among the poor and ignorant, the more flourishing becomes the trade of the nostrum monger and blatant, impudent quack, from whose advertisements philanthropic newspapers derive so large a part of their incomes. Although the column or more of obscene quack advertisements, which up to lately was always to be found in one London popular weekly organ, seems now to have been struck out, it is not noticeable that the number of quack advertisements of any kind has much diminished in any of the papers since the publication of enlightening portions of the evidence before the Select Committee on Patent Medicines and the issue of the second series of "Secret Remedies."

to be taken back to the old principle of paying patients which has always been favoured by the King Edward and Metropolitan Hospital Sunday Funds?

LEADING ARTICLES.

SEASIDE RESORTS AND HEALTH.

THE annual summer exodus to the seaside naturally brings to the professional mind the sanitary aspects of the seaside resorts which his patients, and haply he himself also, may elect to patronise. From time to time, rumours of a disquieting nature reach the world through the medical or lay journals with regard to this or that sanitary defect in more or less fashionable and popular watering places. Outbreaks of enteric fever occur from time to time, usually through some fault in the water supply. Many of our readers will be able to recall the case of a large seaside town on the south coast which has never regained its prosperity after an experience of this kind. In spite of such warnings the water supply of certain resorts is still notoriously bad, and it would be possible to mention an important town depending upon summer visitors for a substantial share of its prosperity where the water supply of a considerable part of the central district is derived from ancient wells. Then, again, the house and general drainage system of many seaside towns is, to say the least of it, unsatisfactory from the point of view even of a low modern sanitary standard. Towns on the seaboard are in many instances necessarily built upon a low

anatomical and experimental facilities at our disposal before advocating universal adoption of a new anæsthetic method.

The Awakening of China.

In our issue of August 7th, a brief notice was given of the career of Dr. G. E. Morrison, who, after serving for many years as correspondent of the *Times* at Peking, has lately been appointed to a position which, although not yet designated by a specific title, is understood to be that of confidential adviser to the Chinese Government. Dr. Morrison is now in England, and to the *Times* of Friday last he contributes an extremely important letter on the present position and future prospects of the new Government. There hardly exists any authority on Chinese affairs whose opinions can carry more weight. He takes an optimistic view. He believes, in short, that there is going on a real awakening among the people of China, and states solid facts to establish his statement. For instance, he points to the change that has taken place in the administration. Under the old régime no man could hold office in the province of his birth; now most officials are natives of the provinces in which they are serving. The interests of the province are thus better served than under the old system, when officials had as their main object the amassing of the largest fortune in the shortest time. For the first time the people who pay the taxes have a voice in the expenditure of their taxes. Dr. Morrison points out that these changes have involved the re-casting of the whole internal machinery of government, and urges that the comparative smoothness with which it has been effected inspires hope in the future of the country. The awakening of China cannot fail to prove an epoch-making fact in the history of the world. With the broader issues involved medical journalism has little to do. It will, however, have some effect upon the medical profession. At present the vast population lives practically without the aid of scientific medicine and surgery. We are already hearing of a growing demand for doctors with European qualifications, and there can be no doubt that until an adequate supply of Chinese medical men can be educated, there will be room for a large number of foreign practitioners, besides professors and teachers in colleges and medical schools. It would be most valuable if Dr. Morrison could supply us with information on this subject, and we venture to submit the suggestion to him.

Measles in Stepney.

In his recently-issued annual report, Dr. Thomas, Medical Officer of the Borough, publishes some remarkable statements with regard to the prevalence of measles in Stepney. Last year the number of deaths amounted to 291, the highest on record in the history of the borough, exceeding the average by very nearly 30 per cent. In the past twenty-two years there have been 4,398 deaths from measles, an average of just 200 per annum, and the excess of 91 recorded last year forms a somewhat startling fact. Comparing the havoc wrought by measles with the mortality from other diseases, Dr. Thomas points out once more that the deaths from this one cause amount almost to as many as those from scarlet fever, diphtheria, and typhoid fever combined; and he emphasises the fact that the harm done by measles is not measured alone by the number of deaths; when not fatal, it often leaves behind the seeds of future trouble, such as retarded growth and defects of hearing and sight. Dr. Thomas seems inclined to the opinion that steps should be taken for the segregation of

children when once the symptoms of the disease have made their appearance. Measles may be said to be virtually a harmless and rarely mortal disease among the wealthy and well-to-do. Dr. Thomas does not seem to have alluded to the fact that in places like Stepney, poverty, bad housing, and the innocent ignorance of poor mothers in all that concerns the proper care of young children, need always to be considered as potent factors in causation of child mortality.

The Health of the Navy.

ON many occasions during late years, in discussing problems of health in the Navy, and especially with regard to the relatively large number of phthisis cases, the question of ventilation in the modern warship has been touched upon in these columns. The whole question was ably dealt with by Fleet-Surgeon C. Marsh Beadnell at the last Health Congress in a paper which we are now glad to see is published as a pamphlet. It seems evident that the designers of our men-of-war have directed their attention too closely to the construction of fighting machines, and have thought too little about the health and stamina of the crews, whose efficiency forms the prime necessity for the successful working of these machines. Without forced draught the allowance of air per man in a modern battleship is stated to be often as low as 86 cubic feet, whereas in barracks the soldier is allowed 600 feet. The remedy is, of course, to be found in artificial ventilation. In active service during war, as was found in the Japanese navy in the late war with Russia, compartments and hatches may have to be kept closed for long periods. To the foul air thus prevailing below the Japanese surgeons ascribed a great deal of the sickness, including dysentery, among their crews in the fleet off Port Arthur. The difficulties in the way of warship ventilation are, however, not insurmountable, and in the newer Dreadnoughts vastly improved conditions are expected. In these ships air will be passed through tanks containing steam pipes, the steam being under pressure. The effect of this will be to dry the air as well as to warm it, and therefore the men will not be tempted to plug up the ventilating louvres, which, as usually fixed, give rise to disagreeable draughts. As regards food, Fleet-Surgeon Beadnell thinks that the diet of the average sailor is perhaps too liberal, and the same view was expressed two years ago by Admiral Moresby.

Arsenic and the Menstrual Function.

THE affinity between the organic and the inorganic is never so well illustrated as in the chemical analysis of the various fluids and tissues of the human body. The localisation of certain metallic bases to special organs and fluids serves a specific purpose, though the reasons for such distribution have not as yet been fully explained in all cases. The existence of arsenic in the menstrual fluid was demonstrated by Gautier, who found that an average of 0.15 mg. is excreted at each menstrual period. It is even more surprising to note that the presence of minute quantities of arsenic in the uterine endometrium during menstruation has been shown by Drs. I. and J. Ries (*a*), who obtained positive results with the Marsh and Gutzeit tests. Immediately after the flow the arsenic is lacking, but it reappears later in the interval, being present in greatest amount just before the onset of menstruation. No arsenic was discovered in the uterine mucosa of a woman of sixty-five. The theory of the investigators is that the metal, small quantities of which are taken in with the food,

is stored up in the uterine glands, and is discharged in the mucoid secretion of the pre-menstrual stage. It is suggested that the arsenic received in this manner in childhood is utilised in the building up of the body tissues, but that at the age of puberty some excess has accumulated. The uterine glands then commence activity, storing up the arsenic until sufficient concentration has taken place for it to act as a poison, consequently the discharge occurs. These interesting experiments are not intended to be a conclusive explanation of the complex phenomenon of menstruation, though they are most suggestive.

PERSONAL.

H.M. THE KING has been graciously pleased to appoint Major James Davidson, M.D., of the Indian Medical Service, to be a Companion of the Distinguished Service Order in recognition of his services in connection with the recent operations against the Abors on the North-Eastern Frontier of India.

MAJOR M. H. G. FELL, R.A.M.C., has been appointed to be a Deputy Assistant Director-General at the War Office.

MAJOR W. SELBY, I.M.S., has taken up duty as Principal and Professor of Surgery at King George's Medical College, Lucknow.

DR. ENID WALTERS, M.D., B.Sc., has been temporarily appointed School Medical Officer to the Bromley Education Committee.

DR. JOHN J. DENNEHY, M.B., B.S., N.U.I., has been appointed Superintendent Tuberculosis Medical Officer for the County of Waterford.

CAPT. J. S. PASCOE, R.A.M.C., has been selected for appointment as Specialist in Midwifery and Diseases of Women and Children to the Woolwich District.

DR. J. ELSDALE MOLSON, of Goring Hall, near Worthing, has been adopted as prospective Unionist candidate for the Gainsborough Division of Lincolnshire.

DR. ROBERT W. MURPHY, M.D., B.Ch., B.A.O., D.P.H.Dub., has been appointed Assistant Medical Inspector of Schools to No. 1 District of the North Riding, Yorkshire.

DR. ALISTER T. MACKENZIE has been appointed Administrative Medical Officer and Principal of the College of Hygiene at Dunfermline, under the Carnegie Dunfermline Trust.

MR. REGINALD STATHAM, M.R.C.S., L.S.A., of The Hall, Cheddar, Somerset, was recently the recipient of an engraved silver casket containing a sum of money as a mark of esteem and respect from his many friends and patients upon the occasion of the celebration of his silver wedding.

DR. THEODORE LEIGHTON PENNELL, M.D., F.R.C.S., of Bannu, on the North-West Frontier of India, medical missionary under the Church Missionary Society, who died on March 23rd, aged 45, left estate valued at £25,202 gross, with net personality £25,160.

MR. JOHN JEFFREY, F.R.C.S., of Jedburgh, Roxburghshire, has been appointed by the Secretary of State for the Home Department to be one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of Berwick, Roxburgh, and Selkirk, and to be attached more particularly to the County of Roxburgh, in place of Dr. W. Jeffrey, deceased.

A CLINICAL LECTURE

ON

SELECTING THE ANÆSTHETIC. (a)

By J. D. MORTIMER, M.B., F.R.C.S.,

Anæsthetist, Royal Waterloo Hospital, Throat Hospital (Golden Square), St. Peter's Hospital, &c.,
 Instructor, Medical Graduates' College.

It is by no means unusual for an anæsthetist to be asked, "Are you in favour of ether or chloroform?" or "What are you going to give?" If he replies, "Sometimes the one, sometimes the other," or, "I do not know until I have examined the patient," his answer evidently causes some surprise. It may even happen that the surgeon or practitioner concerned will urge the employment of an anæsthetic or of a method from which the anæsthetist cannot under the circumstances expect satisfactory results.

The selection of an anæsthetic suitable to the patient and to the operation is, however, a very important part of the anæsthetist's duty, and in the hope of causing this fact to be more generally appreciated this lecture is now given.

The following are the chief points which have to be borne in mind: the safety of the patient, immediate and remote; the patient's condition, general and local; the nature and probable length of the operation; the position; the experience of the administrator: secondary considerations are such as the ease of administration and the portability of apparatus. During an operation the anæsthetic or method may have to be changed in accordance with the state of the patient or the surgical proceedings.

It need hardly be said that the welfare of the patient is the prime consideration, but this is often regarded in too limited a sense—i.e., with the view of guarding against an immediate fatality, but without much heed to other possibilities. For instance, if ether be given from an inhaler to a stout emphysematous person for a prolonged abdominal operation the net result is not creditable when, although the patient is alive at the end, she is in a semi-asphyxiated condition with a probability of broncho-pneumonia following—to say nothing of the impediments and delay which are likely to have disconcerted the surgeon. No doubt if the administrator be inexperienced he will be wise to choose his anæsthetic mainly on the ground of immediate safety, or perhaps to select one with which he has more familiarity than with others; but I venture to say that it is only in emergencies that such a one should undertake the task at all—especially when the state of the patient or the proceedings of the surgeon are likely to cause complications; and there is always the risk that he who is not accustomed to giving anæsthetics may regard as a simple case one in which an experienced administrator would foresee considerable difficulties and dangers. I would remind you that avoidable disasters may (apart from other considerations) put the administrator in a very awkward position from a medico-legal point of view.

It will save repetition if we consider the question of safety, the state of the patient, the proposed operation and position, with reference to those anæsthetics which are commonly used.

Nitrous-oxide (N_2O).—This is usually indicated for short operations, and in all but exceptional

instances is free from danger and without any after-effects. It is not, however, satisfactory when stiffness or jerking would interfere with the operation as in tenotomy—nor when pain from the operation is likely to persist for some minutes. Children are apt to be frightened by the apparatus; the available period of anæsthesia in them is very short, and may be accompanied by micturition or defæcation, or followed by sickness. In the anæmic insensibility is also very transient after removal of the face-piece, although "sandwiching" air during induction will slightly prolong it.

Nitrous-oxide is risky in advanced pregnancy and dangerous in two conditions: (1) In which there is respiratory difficulty, especially if this be due to swelling, which will be made worse by venous engorgement—e.g., faucial abscess; (2) in which there is already obstruction to the circulation or enfeeblement of the heart as in mitral stenosis, in the "Munich-heart" of beer-soakers, in elderly people with chronic bronchitis and emphysema. Nitrous-oxide and oxygen is better suited to such patients, and it may also be used in others to avoid rigidity and jactitation and prolong anæsthesia. Prolonged nitrous-oxide and oxygen has been recommended for diabetics (to avoid coma) and in cases of exhaustion (to avoid shock). It is, however, difficult for even an expert to maintain a level anæsthesia free from rigidity and sickness—which are, of course, objectionable in abdominal operations especially. Nitrous-oxide is often useful to start the anæsthesia in nervous patients, as it is not unpleasant to take and consciousness is quickly lost.

Ethyl-chloride (E.C.).—This also gives a short anæsthesia, but slightly longer than nitrous-oxide. Usually there is general relaxation, which is an advantage to the operator. Recovery is not so rapid and there is more liability to headache, confusion and sickness. Although fatalities are rare, it is unquestionably less safe than nitrous-oxide, lowering the blood-pressure and causing early abolition of the palatal and laryngeal (cough) reflexes, and if a sudden inspiration be taken or if a re-application be made there may be much respiratory spasm. It should therefore be used with caution in operations about the throat and in weakly subjects. It is not recommended for muscular adults, especially alcoholics; for, besides other risks, they are apt to be unmanageable and pugnacious when recovering. For longer operations it has no advantages.

Ether.—It may be said in general terms that for any operation of more than momentary duration this should be given, provided there is no contra-indication. For a comfortable and speedy induction it may be preceded by N_2O or E.C. In emergencies, when skilled assistance is lacking, it is best to put the patient fully under ether when not contra-indicated; much may be done in safety before consciousness returns.

Discussion of the method—whether "open" or by inhaler—hardly falls within the scope of this lecture, except for the reason that lately the former has been highly recommended by some for all

(a) Lecture delivered at the London Polyclinic Post-Graduate College.

kinds of operations, and especially for abdominal ones. It is largely used in the United States; to some extent for the reason, as I am assured by American practitioners, that skilled anæsthetists are not so usually employed as in this country, the anæsthesiation even in hospitals being often conducted by a student or perhaps a nurse. Surgeons have objected to the use of an inhaler on the ground that cyanosis, cough, and exaggerated breathing are harmful to the patient and inconvenient to the operator, particularly in abdominal work, besides causing ill-effects afterwards. But in suitable subjects and with a competent anæsthetist these troubles should not occur. In any case it need hardly be said that the apparatus should be clean, and the face-piece should be frequently removed and the bag emptied. The "open" method has certainly this advantage, that it may be given with immediate safety and probably without great difficulty by those who have no special skill or experience—but those who can attain equally good results by more convenient and effectual methods will hardly be inclined to discard them entirely in its favour. Apart from this, the "open" method is extremely valuable in cases of exhaustion and shock. Oxygen may be given in combination.

Ether should not as a rule be given to infants and young children, in whom it excites much mucous secretion which may embarrass breathing or go on to bronchitis. Elderly people do not usually take it well on account of the degenerated state of their respiratory and circulatory systems. Patients who are fat and full-blooded, heavy smokers, and people whose mouths and throats are in an unhealthy state, are likely to cough and secrete much mucus; if the operation be long, cyanosis and other respiratory troubles will occur, which are not only objectionable at the time but may lead to bronchitis or broncho-pneumonia, particularly if the operation or the bandages interfere with coughing and clearing the lungs afterwards. It is contra-indicated when any respiratory disorder already exists, and is not usually the best anæsthetic when this function is affected by the patient's position during operation. The addition of oxygen does not annul ill effects in unsuitable subjects.

For operations about the nose and throat, ether has the advantage that the sitting position is permissible. On the other hand, vascular engorgement and mucous secretion may interfere with the surgeon's work. This is also the case in such operations as removal of cervical glands.

For abdominal, renal, and mammary operations ether may be given to some patients with advantage, but in a large proportion it will be found better to change after induction to a chloroform-ether mixture (C.E.) or to chloroform, or to give such from the beginning, for the reasons already stated. After operations on the kidney and in the upper part of the abdomen there is, as was shown by Dr. Pasteur (Medical Society of London, 1911), inhibition of the action of the diaphragm, which may lead to basic pulmonary collapse, and this again may go on to broncho-pneumonia. Ether is not, as was formerly supposed, the direct or sole cause of this disorder, but it may be an indirect or contributory cause, and should therefore be avoided or used with caution when there are other unpreventable factors.

In operations where much hæmorrhage is possible, as in those on the thyroid, I am doubtful whether the advantages in lessening shock may not be counter-balanced by increased loss of blood and over-stimulation of the heart.

Ether, and ethyl-chloride, must not be used,

especially by the open method, if a cautery or lamp has to be brought near the patient's face.

Chloroform can be best taken by robust patients in early life and old age and by healthy women during parturition. However, infants, children, and pregnant women have not, as was formerly thought, any special immunity; although the usual absence of degenerative changes may enable them to be rescued from perilous conditions without much difficulty. It is a convenient (sometimes an essential) anæsthetic for operations about the nose, mouth and larynx, and in some respiratory disorders. The sitting position ought not to be adopted, except for special reasons, and when the administrator and operator are experts. It is particularly dangerous in dental operations. On the other hand, it may be given with more than usual confidence if the Trendelenberg position be chosen. It should not be given when shock is either present or expected, and it must be used with much caution, and combined with oxygen, when breathing is for any reason unsatisfactory.

During the last few years attention has been drawn to the "status lymphaticus" as being one in which chloroform is peculiarly dangerous. Authorities are by no means agreed as regards the possibility of diagnosing this condition during life, and it can only be said that chloroform should be avoided if there be the slightest reason to suppose its existence—indeed, it is a good working rule never to give chloroform except for certain special reasons to anyone unless health is not merely average, but above the average.

The condition which has been called "delayed chloroform poisoning," and is associated with acetonuria, is also unsettled as regards its pathology. Meantime it is well to act upon the rule just given and especially to avoid giving chloroform to diabetic patients, or fat, rickety children, or in acute septic cases, such as appendicular abscess, in which the liver will already have been disordered, and some degree of carbohydrate starvation taken place. Leaving out of consideration this special danger, it is better not to give chloroform to any patient who is from constitutional peculiarity, or from the operation or the disorder for which it is performed, likely to have much after-sickness, for this will probably be thereby intensified.

Chloroform-ether mixtures (C.E.).—These may be regarded as filling the gaps, and as applicable to conditions in which neither ether nor chloroform alone would be altogether satisfactory. The proportions may be varied according to requirements, approaching (open) ether on the one hand or chloroform on the other, but usually two parts of chloroform are combined with three of ether (the old A.C.E. without the alcohol). Such a mixture should be used with the same strict caution as chloroform—that is, it should be renewed frequently and in small quantities with free admission of air, undeviating attention being given to the pupils, colour, pulse, and particularly to the respiration. Given in this way it acts satisfactorily in average or weakly patients near the extremes of life, in the alcoholic and wheezy, in those suffering from various respiratory, cardiac, or abdominal disorders, for abdominal, mammary, and renal operations, and may precede chloroform when this is needed for the nose or larynx, also at the beginning of etherisation for nervous people who object to a face-piece or to the smell of the unmixed ether.

There is much less probability of serious reflex respiratory or circulatory shock on manipulation of the viscera when ether or C.E. is employed than when the patient is under chloroform, and, if this does occur, far less difficulty in restoration. Rigidity is more safely and easily overcome than

by chloroform. In my experience, after-effects of C.E. in the majority of cases are absent or slight.

In an article published in the *West London Med. Chir. Journal* (January, 1907) I drew attention to a danger apt to arise during suprapubic prostatectomy—namely, a disturbance of the respiration and of the circulation consequent on distension of the bladder; and also to a difficulty (reflex rigidity of the abdominal and perineal muscles) which may considerably hamper the surgeon during enucleation even under full anæsthesia. With a more extended use of C.E. instead of chloroform I find these troubles seldom occur.

"Mixed" or "Combined" Anæsthesia.—By this is meant the use of a general anæsthesia when sedative drugs have been given previously by hypodermic injection. The method is of value (1) to calm the patient, especially in cases of exophthalmic goitre, or when there is severe pain and shock, and generally in neurotic subjects. (2) To save the anæsthetic and lessen reflex disturbances. (3) To lessen after-pain and restlessness. Morphine or opium should be combined with atropine, to get the effect of the latter drug on the cardiac and respiratory functions and on secretion of saliva and mucus. I have found scopolamine to be somewhat uncertain. Here, too, discrimination and caution are needed. If possible, the susceptibility of the patient should be tested beforehand, or the drug should be given in divided doses—otherwise, when the general anæsthetic is added, there may be dangerous depression. The risks are increased when there is much feebleness or lethargy, and in most forms of respiratory, renal, or cardiac disorder, and, I think, liability to after-vomiting and intestinal atony is certainly not diminished.

Spinal Analgesia.—This is indicated for operations on the lower limbs and in the abdomen, especially below the navel, when there is some objection to general anæsthesia, i.e. :—

1. Shock, present or expected.
2. Some respiratory affections—e.g., bronchitis.
3. Diabetes.
4. Alcoholism.
5. Operations which set up reflex disturbances (rigidity, etc.) even under deep general anæsthesia.
6. When there have been dangerous effects, or after-effects, such as persistent vomiting, as a result of a former anæsthesia, if such cannot apparently be avoided.
7. When there is strong objection by the patient to loss of consciousness.
8. In some emergencies, when no skilled anæsthetist is available.

It is contra-indicated by :—

1. Affections of the spinal cord.
2. According to some, by sepsis, and toxæmias such as syphilis; also tuberculosis—there being some risk of meningitis (diminished resistance at site of puncture).
3. Nervous and excitable patients—and usually in conditions such as marked anæmia, cardiac disease, status lymphaticus, old and feeble patients, pregnancy, when any emotional tension may be harmful.

In regard to the last group, combination of light general anæsthesia with spinal analgesia is sometimes very useful—thus obtaining flaccidity and other advantages of the latter without mental shock, whilst the danger of a deep general anæsthesia is also avoided.

Local analgesia may also be combined with general anæsthesia, with the effect of considerably saving the latter and lessening shock, whilst avoiding pain and mental disturbance—for instance, in the operation for deviated nasal septum.

As an illustrative case, I will give you that of a man of 51, requiring removal of his prostate. He was purple-faced and extremely "nervous"; probably a chronic alcoholic. Anæsthesia was induced with C.E. for the reasons already indicated, and then a spinal injection given of .15 gm. novocain. The prostate being small and adherent, enucleation was difficult, but there was no reflex rigidity whatever, although he was so tightly under the anæsthetic that consciousness was hardly lost. Under spinal analgesia alone he would probably have fainted, or interrupted the operation by struggling. Under general anæsthesia alone even a dangerously deep narcosis would probably not have abolished rigidity and shock.

There are methods such as prolonged nasal administration of nitrous oxide or of this with oxygen (for dental operations), and intravenous anæsthesia, which should only be attempted by specialists, so I will not discuss them at length. But, as to the last, I will say that its employment needs very full consideration with regard to all the circumstances mentioned early in this lecture, and that it is by no means so free from difficulties and dangers, nor has it in most instances such great advantages as may have been expected.

Much more might be said, but my time is limited, and your patience cannot be inexhaustible. However, I trust I have made it evident to my audience that a method which may succeed well in one instance may fail badly in another, and that no anæsthetic nor apparatus should be used as a matter of routine. As once truly remarked by Mr. Marmaduke Sheild, "Every case of anæsthesia is a study in itself."

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of this *Journal*. The lecture for next week will be by George Grey Turner, F.R.C.S., Newcastle. Subject: "Perforation of the Stomach and Duodenum, with Special Reference to the Early Symptoms."

ORIGINAL PAPERS.

FRACTURES AT SEA.

By A. G. VAVASOUR ELDER, M.R.C.S.,
L.R.C.P.LOND.,

Surgeon to the White Star Line.

A FRACTURE has been aptly defined as a solution of continuity. First thoughts would lead one to think that a fracture was a fracture all the world over; to be treated in the orthodox manner to obtain the orthodox result. At sea, however, beyond conforming to the above definition, fractures present a totally different aspect to what they do elsewhere to the practitioner called upon to treat them.

This difference is due to three main points :—

1. Ætiology.
2. Appliances available.
3. Conditions under which appliances are used.

Under the first heading it may be stated that the usual text-book classification of fractures being due to either direct or indirect violence is perfectly true in the main at sea. But the analogy goes no further.

On a ship the factors at work in producing a fracture are totally different from those on land. They certainly give rise to a solution of continuity, but this solution invariably takes place in a part not as described in the books. The logical outcome of this is that an instant recalling of anatomical details is imperative; likewise a departure from the orthodox and academic modes of treatment as far as splinting is concerned, if a satisfactory result is to be obtained.

Primarily, it may be stated that fractures at sea are commonly caused by direct violence, not infrequently by a heavy object falling across or hitting the bone in question. This results in a fracture in a part of the bone which may or may not be typical. It also not uncommonly produces a compound condition to add to the confusion. A few instances of such may serve as illustrations. During a slight gale, a young girl attempted to reach the deck on the exposed or "weather side"—incidentally ladies are notorious in making for the windy side on all occasions—by opening the closed "weather side" door and stepping over a coaming about twelve inches in height. With one foot over the obstacle, she slipped on the wet deck, the force of the gale shut the door violently and she fell inwards, being caught by a chance bystander, with her leg jammed between the heavy teakwood door and the coaming. Result:—A fractured fibula only, about two inches below the head of the bone, and in addition a strain on the external lateral ligaments of the knee-joint. The patient was carried to her berth, and at the outset the fracture was not diagnosed. The "spring of the fibula" was apparently elicited, although it caused great pain. This was attributed to the severe bruising the parts had undergone. It was not until twenty-four hours later, on attempting to put the foot to the ground that acute pain was felt. A fracture was suspected and a more rigid examination of the fibula was made throughout its whole length.

On again trying the "spring," it was elicited so long as both hands grasped the lower fragment, but it disappeared as soon as the upper hand got above the site of fracture. A grating sensation was then felt, and also obtained on passive movement of the foot. The upper half of the leg was encased in a removable plaster splint and the whole put in a McIntyre, in which the patient left the ship. The next voyage the splint was returned to the ship with a note that the result was perfectly satisfactory and that the patient was roller-skating.

Another case with similar aetiology in a stout girl of 17, resulted in a "greenstick" fracture of the middle third of the shaft of the fibula with a chipping of the bone at the site of impact. Diagnosis was only made by X-rays on shore two days after the accident, when a longitudinal crack and a small spicule of bone were clearly defined.

A boy was standing underneath an open hatchway through which baggage was being hoisted on deck on a grating. The rope broke, and the grating fell about twenty feet, catching the boy's leg in the centre. Both tibia and fibula were snapped clean across, the lower fragments presenting through the wound. As this happened in port, first aid only was rendered, and subsequent recovery in hospital was uneventful.

Fractures following upon persons falling or slipping on wet decks during heavy weather are also likely to be atypical. This is due to the angle of the deck and possible obstructions met with in the track of the patient's slide. The following is an interesting case of this nature.

A child, aged 11, slipped along a wet deck and was "brought up" in his slide by a ventilator. When picked up, he was found to have sustained an impacted fracture in the middle third of the right femur. Just when the fracture occurred it is impossible to say, but contact with the ventilator must have impacted the fragments. Under chloroform the impaction was reduced, and the thigh put up in a double-inclined plane splint. A very good result was obtained with practically no shortening.

During a cricket match on deck—a frequent source of casualty—one of the players came into violent collision with a wire funnel-stay and fractured his left clavicle almost in two exact halves.

Another peculiar accident occurred in which a

sailor was struck on the back of the left shoulder. In this case, however, no fracture took place but simply a dislocation forward of the first and second left ribs. The clavicle was unaffected.

The second and third points in relation to fractures at sea are best dealt with together for the sake of clearness. Referring to the appliances at hand for the treatment of fractures, from the foregoing remarks on the subject of aetiology, it will be seen that some modifications are bound to be called for in putting them up.

The legal equipment of a ship coming under the Emigration scale consists of:— 1 McIntyre splint, adult size; 6 sq. ft. of cardboard; 1 or more sets of wooden splints for leg, thigh and arm; plaster of Paris bandages of varying quantity; Gooch splinting, also in varying amount according to numbers carried.

The above is quite a formidable list, yet it is few cases of fracture which will not require the assistance of the ship's carpenter to make splints for the occasion. These will have to be devised by the surgeon according to anatomical relations which are probably of an unorthodox nature.

In addition to abnormalities of fractures as far as those of the lower extremities are concerned, their successful treatment is further complicated owing to the absence of a steady platform. Few vessels, indeed, are fitted with swing fracture-cots. It requires ideal weather conditions, even in a large ship, to avoid a slight though continuous lateral movement of the patient as he swings in his bunk. The vibration of the ship is also not without effect upon a fracture.

Thus a lower limb must not only be immobilised in a splint, but the splint and patient must be made immobile in the bunk. The use of pulley and extension weight is also affected by the roll of the ship. It causes a series of jerks on the lower fragment as the weight swings to and fro by gravity, and it is sometimes painful to the patient. In fact, a pulley and weight are best omitted if not seriously indicated.

If extension is required and site of the lesion permits, then it is best applied by putting the patient's boot on. Two rings or hooks are screwed into the heel and forward part of the sole. These are connected by a wire or cord, to which the extension rope is fastened at the proper angle, and then led through the pulley at end of bunk. This method has proved far superior to the orthodox stirrup made with adhesive plaster. For the tropics it is especially good as the boot can be taken off to permit cleansing of the foot. Sticking plaster, under these conditions, is liable to slip and cause irritating dermatitis. In fact, it should never be used in the tropics for this reason.

A Salter's Cradle can be made by knocking the bottom out of a good sized soap-box, and suspending the injured limb from the frame so obtained. It is a better and more comfortable method than that of slinging the leg from the berth above as is sometimes done.

For general purposes, a removable plaster of Paris casing makes the best splint. It takes a longer time to apply than any other and the process is messy, but it has the advantage that once it has been properly moulded, it is always *in statu quo ante* after removal for massage. Where this method is contra-indicated, the best alternative is that of the double-inclined plane adapted for ship use. Here two points must be borne in mind. The first is to fit the planes to the patient, and then to make them and the patient immobile in the bunk, or as much so as possible.

The former is obtained by careful measurements taken from the sound limb. Two pieces of board,

a little wider than the limb in its varying parts, are hinged together, the angle between them being regulated at will by an eye-bolt on each flap, connected with string. On these base-boards, side-boards are accurately fitted, so that the limb is encased on three sides. The inner thigh board must be made shorter, fitting up to the crutch, while the outer one should extend up to the anterior iliac spine. Packing is added where required with Gamgee tissue which is found among the medical stores. A top piece, well padded, is then placed over the seat of the lesion if necessary, and is kept in position by bandages or straps.

To fix the apparatus in the bunk, a cross-batten is nailed to the bottom of the foot-piece, projecting about nine inches on either side. The thigh piece has a similar batten on its outer side only. With this arrangement a "slipper" can be used. If wanted, more extension can be applied to the lower fragment in the ordinary way. Additional immobility is obtained by sand bags on both sides of the patient's body.

A. Leg flap. B. Thigh flap. C. Leg side pieces. D. Thigh side pieces. E. Splint over site of fracture. F. Rolling chock for leg flap. G. Rolling chock for thigh flap outer side. H. Hinge. J. String to regulate angle of flaps.

The diagram explains itself, and the whole can be made and fitted within half an hour. This method is especially useful for children, as by it they are completely mobilised. For them, too, a Bryant's Box is contra-indicated, owing to the roll of the ship. It might be added that for a fractured femur a long Liston's splint is not so satisfactory or comfortable for the patient. With the rolling of the ship, the patient rolls in his splint, and complete rest is not obtained.

As far as the author's personal experience goes, fractures of the upper extremity do not diverge so greatly from the orthodox as those of the lower. They do not call for any special mention further than to draw attention to the possibility of abnormal anatomical relations brought about by abnormalities in the form and direction of the violence producing them.

In conclusion, it may be added that the ship's sail-maker should easily be able to make a canvas swing cot and the carpenter to fit it with bottom boards. It may not be out of place to remind ship surgeons of the nursing side of their nautical duties in avoiding the incidence of boils and bed-sores in their patients. (a) Frozen food, even after three or four weeks, is undoubtedly a predisposing factor, if not the sole one in their formation. To the recently

discharged house officer, nursing details are apt to assume a minor importance in cases, owing to the presence of a nursing staff to perform them. At sea, however, the surgeon is usually the sole professional man on board, and must combine nursing with medical duties.

THE TREATMENT OF SYPHILIS.

By PROF. GAUCHER, M.D.,

Professor of the Clinic of Skin and Syphilitic Diseases in the Faculty of Medicine, Physician to the Hospital St. Louis, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

So many errors have been published within the last few months on the treatment of syphilis, that I believe it necessary to fix the therapeutics of this malady and to teach you, as it is my duty, what should be done and what should not be done, what is useful and what is useless and even dangerous, what may be expected from a treatment and what it cannot give. You will easily understand that it is not alone the classical treatment I am going to expose to you, but this new remedy which has been so widely advertised as a panacea for all the manifestations of syphilis.

I have returned from the Congress at Rome where I heard every opinion expressed, where I took part myself in the discussion, and now I place before you the conclusions of this discussion which had been resumed in measured terms by Prof. Finger (Vienne). "The 606 does not sterilise syphilis; the relapses after the 606 are more frequent than after the usual mercurial treatment." This is what I claimed for the last 18 months, and I was glad to see that my opinion formed at the first is now adopted by the great majority of syphilographers.

Here is the truth about the 606: It is a remedy for special cases endowed with very rapid cicatrising power. Every syphilitic ulceration at any period, the most ulcerating chancres, the most obstinate mucous patches, the profoundest tertiary ulcerations, are cured and cicatrised very rapidly by arseno-benzol, with more rapidity than with iodide of potassium or mercury, in the generality of cases, but not, however, in all. The 606 possesses consequently a very rapid cicatrising power, but that is all.

These ulcerations once healed always relapse if they belong to a period of syphilis where the lesions frequently return, that is to say, mucous patches, secondary ulcerations or primary chancres; the chancre re-appears frequently at the end of two or three months. On the other hand, tertiary ulcerations seldom return, but it is thus with the other remedies for syphilis.

In reality the 606 is deceptive; it only cures for the moment, produces in no wise sterilisation of the disease even where the injections are made at the very outset. A third of cases of syphilis present little more than the chancre, a fugacious rash, a few mucous patches which get well easily or pass unnoticed. It is among these benign cases that twenty years after we find tertiary accidents of varied forms. The 606 does not consequently cure syphilis, it only cures the syphilitic ulcerations. But it possesses on the evolution of the disease a very curious retarding action which contributes to make it a *perfidious remedy*.

I have already said that the chancre may return after a period of two, three or six months; an analogous phenomenon is observed after injections made during the secondary period. The mucous patches cicatrise with amazing rapidity, the skin and the mucous membranes are cleaned off in a few days in a really surprising manner, but they return at the end of a few months with intensity

(a) See the Author's work, "The Ship Surgeon's Handbook," Second Edition, 1911. Price 5s

and under a form unusual to observe at this period. I saw in women treated by injections of arseno-benzol at the very outset of the disease, the mucous patches return at the end of a year or 18 months, that is to say, at a period when in syphilis properly treated with mercury, the patches no longer, so to speak, existed. Arseno-benzol is thus but a drug to be only occasionally employed, and its indications are very limited; it may contribute to render the disease latent, but it does not cure.

If you employ the 606 to heal more rapidly the chancre, you should warn the patient of the possible return of the sore several months afterwards; if you use it against the mucous patches, you must not be surprised if you see them return and more tardily than in syphilis abandoned to itself.

The first indication of the German specific is limited to the cicatrisation of the chancre or the mucous patches; the second is more important. In cases where mercury is without action or where this action is exhausted after prolonged use, the treatment by arseno-benzol is legitimate. It is also legitimate in case of intolerance for mercury. But it should be borne in mind that the 606 acts only on the cutaneous ulcerous lesions and never on those of the quaternary period: ataxy, general paralysis, leucoplasmia.

In any case, when you may judge it necessary to employ the remedy I advise you to employ small doses, after assuring yourselves of the integrity of the viscera, especially of the kidneys, the nervous system, the eye and the ear; I counsel you to use it with fear and trembling as it may be very dangerous even in small doses, without knowing why. It is needless to go into all the theories invented to explain the causes of death from the 606; the cause is simply arsenical poisoning. The patients succumb with generalised visceral congestion, particularly of the kidneys, as in animals poisoned with the 606.

Like all organic preparations of arsenic, the 606 is fatal to the kidney; it is particularly dangerous when this organ is already affected, but it is capable by itself of producing toxic congestive nephritis. It is also dangerous for the nervous system, manifesting itself by the production of an abundant rachidian lymphocytosis.

I had to treat a case of polyneuritis due to injections of salvarsan as well as several cases of deafness and noises in the ears, and one still more grave—complete cecity from optic neuritis.

Arseno-benzol has caused more deaths than syphilis abandoned to itself could produce; recent syphilis is not fatal, and when one speaks of succumbing to syphilis, distant results are meant: cancer of the tongue, general paralysis, ataxy.

The conclusion of all I have said to you is:

The 606 may be very dangerous without knowing why, hence it should be used with caution.

The 606 possessing but a limited and momentary action, it should not be regarded as an habitual treatment of syphilis.

The treatment of syphilis remains consequently what it was before—viz., mercury and iodide of potassium. The best mode of administering mercury is that of injections and the best preparations are those of the soluble salts, benzoate or biniodide of mercury. Where injections are not accepted, rubbing in for twenty minutes of strong mercurial ointment is the next best treatment. A drachm of the ointment is rubbed over a limited space on the side of the thorax and transferred to the opposite side every second day.

Administration by the mouth is inferior to the subcutaneous method but sufficient for ordinary cases, especially when the disease is treated during

the first two or three months by injections. For it must be remembered that the most important treatment is that of the *début*—that is to say, during the period of active virulence.

The preparations to be employed by the mouth are: corrosive sublimate in pills or lactate of mercury in solution. The pills are composed of sublimate and extract of opium, one-fifth of a grain each, and the dose is two daily. The solution of lactate of mercury is of the same strength as Liq. Van Swieten (1-1,000), the dose is one dessert-spoonful twice a day. With these preparations you can treat every case of syphilis in all its stages.

If you are called to treat a case of syphilis at the very outset you will act as follows:—

a. During the first month you will give an injection of 2 centigrams of benzoate of mercury each day.

The following month an injection of 2 centigrams every two days.

b. After one month rest, a month of pills with corresponding rest, and so on for two years.

The third year the pills will be given one month followed by two months' rest.

The fourth year, one month in each six months.

In all these periods it will be frequently useful to replace for a time the pills by the injections.

A treatment covering four years is generally necessary, even if the reaction of Wassermann is negative. For my part I do not think marriage should be permitted before five years have elapsed. In any case it would be necessary that the patient should undergo a treatment during one month preceding the marriage.

I have already referred to iodide of potassium as an auxiliary to mercury. What are its indications? Iodide of potassium is only an adjuvant of mercury, it is a resolute agent useful in all the periods of the malady, against rebellious lesions, extensive, grave, menacing or against infiltrating lesions. You will prescribe it associated with mercury in phagedenic chancres, in papulous, tuberculous syphilides, gummata and visceral manifestations, especially in nervous affections. It is employed in 2, 3, 4 or 6 grammes per day.

The mercurial and iodide treatment is the basis of the treatment of syphilis in all its manifestations. It is only where this treatment has proved itself to be insufficient that you are authorised to employ organic arsenic.

DEMONSTRATION OF A SYSTEMATIC POSTERIOR PERCUSSION OF THE APICES, AND OF THE "OVAL INTERSPINOUS DULNESS" AS AN AID TO EARLY DIAGNOSIS. (a)

By WILLIAM EWART, M.D. (CANTAB.), F.R.C.P.,
Consulting Physician, St. George's Hospital, &c.

The normal "Oval Interspinous Dulness" is the corrected edition of the original "Interscapular Lozenge-Shaped Dulness," which was imperfectly analysed and too loosely described in the Dorsal Map of Percussion in 1899, and again in 1910. Never unmindful of the value of a dorsal examination of the apices and of the lower apices (which will also be briefly considered), the author's previous diagnosis had hitherto lacked the elementary accuracy dependent upon a familiarity with the *normal field of percussion*, and with the precise boundaries of its normal pulmonary resonance, and of its normal mediastinal dulness. These can now be defined by the pleximeter in their normal individual variations, as a guide to any abnormalities, whether *respiratory*

(a) Abstract of paper read at the Medical Section of the British Medical Association Annual Meeting, July, 1912.

(pleural, pulmonary, etc., including functional irregularities), or *mediastinal* (mainly structural and of varied derivation). *That familiarity is indispensable for the earliest diagnosis* of apical tuberculosis by physical signs; although this is only a small section of the general diagnostic usefulness of the new sign.

For *Apex Diagnosis* the most valuable peculiarity of the oval subresonant dulness is the normal respiratory oscillation of its edges with inspiration and expiration. This affords a *standard* wherewith to gauge the normal, or the deficient respiratory activity of the apex, the latter being the earliest of all morbid events in phthisis. It is also a *test* for the "functional" or the "structural" significance of any apical in-expansion. Again it is the indispensable *differential test* between "local lesions" and "local atelectasis." Its close study opens up an important range of localising observations and of fine indications which are alone adequate for the purpose of early diagnosis.

The *Vicissitudes of the Oval Dulness* under the varied respiratory affections (pulmonary emphysema, asthma, congestion, bronchitis, the pneumonias, the pleurisies and pneumothorax, etc.) are a vast subject to which only a cursory review can be given.

The *Mediastinal Aspect* of the same study, that of the intensifications and of the encroachments of the dulness of the oval patch, is yet more varied in its scope; and this includes an extensive *surgical* range of diagnosis. The chief medical representatives in that group are the cardiac, the pericardial, the vascular, the œsophageal, the neoplastic, and lastly, almost comparable in its numerical incidence with the group of phthisis, the glandular. They all of them react also upon the behaviour of the "retrovascular dulness," of which the oval patch is the upward continuation.

The *Practical Conclusions* are summed up in one statement: The method is indispensable for efficiency in apical and in mediastinal diagnosis. Its practice is a necessity; and this involves the unavoidable adoption of the means which are essential to its success.

THE MATERIAL OBLIGATIONS OF SPIRITUALISM AND ALLIED PHENOMENA. (a)

By T. CLAYE SHAW, M.D., F.R.C.P., ETC.,

Emeritus Lecturer on Psychological Medicine, St. Bartholomew's Hospital, London.

(Concluded from page 188.)

IN his book, "The Other Side," Mr. Horace Vachell gives us an account of a person who was killed in a motor-car accident but whose spiritual existence (which in a letter to me he calls a sort of astral body) was continued afterwards as a "transformed David"; but, just as in "Theokosmia," Mr. Vachell's story is but the assertion and description of a highly-imaginative man who wrote the book in all seriousness, an embodiment of ideas arising in the course of an eventful life, at times far away from the haunts of men and in circumstances calculated to wake the splendour of phantasy for which the author is so well known. Notwithstanding, all ends in nothing—indeed it is more than this, for it assumes what we know to be impossible, the re-vivifying of dead matter, which even the Spiritualists themselves acknowledge to be impossible, for in all their rambles they maintain the necessity of having live matter to deal with, hence the obligation of electric currents. We might just as well expect that if a piece of necrosed femur were placed among the living tissues of the body from which it was

taken it would be again re-constituted and become a living integral part of the living tissues—or to put it in their own way of expression we should expect to see the spirit of the bone re-enter and be incorporated with that piece of bone, a thing which we have every right to say cannot be, for we act on the latter assumption and find it to be true when we use ivory pegs to support disrupted ends of fractures, knowing that though placed in juxtaposition with living structure, the props or supports will never become living matter. If we believe that Lazarus was raised from the dead and lived again in the natural flesh, if we believe that Paul brought Eutychus again to life by breathing upon him, if we believe that Peter brought back Dorcas to life by the same process of breathing upon her, we may do so without crediting the Spiritualists of to-day with powers to which they pretend, of reversing the laws of matter, which laws they own to obtain in the spiritual world. We may say to the Christian Scientist, you profess to cure disease by Faith, but you fail; and in what you call your successes we can supply you with material reasons in obedience to known laws which account for what happens, and are intelligible and will stand the test of experiment in that they can be repeated; we may say to the mediums and the spiritual *séance* professors you show us nothing new, you cannot inform us of anything which promotes the progress of the race, you lead us no further in any spiritual or material path than we now know, and we can account for all you do by ordinary experimental processes. We say that you, an acknowledged inferior creation, attempt to compel the intervention of a higher Power or Force by material processes such as crystal-gazing, and make statements as the result of your reported intercourse which are not true and do not come to pass. We say that your major premiss may be true, but that as you (in your own words) have no possible conception of it, you can draw no conclusions from it because the terms of your argument put you without argument. You, in all your deductions, follow the example of Chanteclair, who attributed the break of day to his own crowing, or like Owen Glendower you attribute earthquakes to a recognition of the fact that he was born. The tendency of modern men of Science and of our own Profession is more tolerant of the possibility of there being a Force, Power, Soul or Mind (by whatever term to like to call it) than it was.

There are among us men who say that they have certain powers over other people, such as Personality, power of Hypnotism, etc., which they claim but cannot explain. There is no doubt that Personality, the attribute of influence, does exist in some people more than in others, but it can be explained without recourse to the supernatural, the laws of which we do not know. There is no doubt that at the word of command some people, not all, will assume a hypnotic condition, but we know that a person who is hypnotised is his own agent, and that under the name of auto-suggestion he can perform the process on himself. I have no doubt that any medical man who practises hypnotism would be the first to acknowledge that he does not possess any peculiar Power in this direction, for it is indeed a physical process which in a greater or less extent may be acquired by anybody, may indeed be taught in a school or clinic of psychiatry. But the public, which is uneducated, rushes into its own way of accounting for what it cannot understand, and attributes the phenomena to a spiritual agency of which nothing is known. The charlatan takes advantage of this, claims that he can disclose things which are in the future, takes the money from those who do not see that however previous the spirit may be there is *no living material of the future*—it is in the present—and so they go away empty or filled with what are at best guesses and deductions from the present. Professor Stout "sees no sufficient reason for being particularly sceptical concerning communication from departed spirits," and Professor J. S. Macdonald has recently stated (see *Physiology*, British Association, 1911) that "there was some loophole for the view that mind was not directly associated with life or living matter, but only indirectly with certain

(a) The Harveian Lecture, read before the Harveian Society, on Thursday, March 28th, 1912.

dispositions of dynamic state that were sometimes present within certain parts of it. Where there was evidence of Mind the view was that it represented a force acting from without upon what was still no more than matter involved in certain chemical and physical states." So that Mind is a Force consisting of such terms as Will, Attention, Truth, Love, Hate, etc., acting upon material which is more or less fitted to receive it and to make it manifest. It is not the same thing as Life, because we have many manifestations of Life without the slightest sign of Mind. The body and brain are mere instruments upon which Mind plays like an Æolian harp under the influence of the wind. The views of Sir Oliver Lodge appear to be of the same kind except that his view of matter is that it consists of ions in *rotational* motion, and that some universal, homogeneous substance in simple *vibrational* motion is Light. Inasmuch, then, as the body has no Will, Attention, Choice, *in itself*, it is but a form of matter, which cannot originate anything, but is the medium through which properties existing external to it can operate, and nothing more. It is a necessary postulate that the more the material is developed the more extensive and diverse will be the field of demonstration of Mind. What then is this Force? Is it when in action the same everywhere? Does it act on the idiot as it does on the intelligent and growing child, and when that child grows, and as it grows, does it still remain the same, and when he becomes a man is it still the same in quantity and quality? Apparently it must be. The hypothesis assumes that ethereal Mind is all *Knowledge*, all *Reason*, all *Choice*, all *Attention*, and that it can operate on a body which is fitted to respond to its vibrations. Development of the body must then precede manifestations of mind; and in this way only can a material body show such functions as will and attention—faculties which are not in it but are displayed by it, the display of which causes the material to think that it is doing it itself. Will, Attention, Knowledge generally are then borrowed plumes—they do not belong to us, we are merely the mannequins on which they are paraded. This initiative force is, however, in some sense material. Lodge called it one universal substance perfectly homogeneous and continuous, so that it must be subject to change and to exhaustion unless it is constantly renewed. Is that the reason why we cannot display certain mental processes for more than a short time? Does the Force get exhausted, or is it the body material which strikes, because it has to function for so long a time? If so, why does not the Body compel the Force to stop before this process of exhaustion comes on? It cannot, on this hypothesis, because it is a driven thing with no initiative of its own. Can it be that this omniscient Force, by constantly working upon a certain part of the Brain, can develop it and leave a part of its Power there, thus giving us some degree of voluntary effort, and of attention, and of other qualities? We may fairly say that as bodily processes are persevered with they do develop, and that the balance of experience in a structure may become determined in one direction more than in another; but this is merely saying that the material for Force to display itself upon is greater in quantity, and does not prove that it has come to possess any new quality, for it has not been shown that Force can alter material; it is hypothecated that the proper material must first be there, else it cannot exert itself. Will and goodness cannot move a stone because the physical conditions of living matter are absent. Force must have living material to act upon, and not only that, but the material must be of the right kind and in the right condition to be acted upon, because diseased living tissue cannot be supposed to be within the orbit of spiritual influence; indeed, diseased material is generally not only of lower vitality than the original, but is of a different kind and structure. According to the teaching of Spiritualists, there are good and bad Spirits which act upon living human material. If a man is good—*i.e.*, has material for good in him, how is it that he becomes (as is very often seen) bad? Is

it that the good Spirit is overcome by the bad Spirit, or is it that the good material becomes inferior in quantity to the bad material which, it is to be presumed, comes then under the influence of the evil Spirit? If so, then the Spirits are under the control of the material and are not (as the Spiritualists say) the developers of the material; for in the case supposed why should the good Spirit, which has it all its own way, allow itself to be caught napping and let another, and a destructive, influence take possession of the field? The whole hypothesis is a fanciful assumption.

If through fear of injury by falling I refuse to climb a hill, Force or external Will does not help me—I remain at the bottom. If, however, I am conducted or helped up and thus taught that there is no danger, I acquire experience and my material basis for knowing that I can with impunity climb is increased; then and only then can the Force or Spirit act, so that Spirit does not create possibility of achievement, it has to wait for material development. In plain fact all spiritual teaching is material—its ideas are either material or non-existent—its experiences are material—its symbols are material—its rewards and punishments are material as also are its metaphors. It is in fact materialism. The man who is called the Agnostic may be the only true Spiritual believer! He it is who says—"I grant the possibility, thereby expressing a Belief in a Force which has powers which I cannot conceive and do not understand, which may have its own laws but is in no way of competency to be regarded as capable of personation by a dove, nor indeed composed of essences which we call good. Therefore I am content to go on building up my body in what seems to me the best way, and when I fail I have recourse to others, whose experience and skill are better than mine to assist me. In the fact of this Power I accept things as they are. I see people suffering from organic disease whose requests to be healed are not granted—they die; these people rely upon what they call 'Faith,' but they obtain nothing of the result which they ask for, and the reason is that they do not know the nature of the God they appeal to, and so may be entirely wrong in their methods."

And so in our profession the man who practices "Suggestion" will do nothing by going on any other assumption than that by constantly repeating what he wishes to impress, he educates his patient to be able to say "I can" whereas before he lived in the fact "I cannot." Since the hypothecated mental functions are not material agents as far as we know and can conceive, but only act through living material which is the compelled and is in no way a compelling agency, and since we avowedly know nothing of the real nature of this Force, which, however, we are content to assume, we can have no mental pharmacopeia, no means of strengthening or weakening Will, Attention, Emotion, even consciousness, except by placing the material in such conditions as we think best fitted to obtain the result which we desire.

We have succeeded, as Science has become extended, in gaining the mastery over some forms of what we call "dead matter" so as to make it the better exponent of what we call electricity and magnetism; we have even succeeded in making the living material body a better exponent of the Force which we call Life; but we are just as incapable of understanding the real nature of Electricity and Magnetism as we are of Life. Without doubt we shall go on improving our knowledge of the scope of action of these various Forces, but that we shall be able to understand and have mastery over the Forces themselves is quite another question. Here is the *argument of obligation* which I do not see that the Spiritualists can get over. These are told that "there shall be no more repetition of these signs and wonders" until a certain time which has not yet arrived. If then they are bound by this declaration—as they must be—how can they explain either the revivification of dead matter as in the case of *reported* ghosts, or the compulsion of Spirit by living material agency as in *reported* conversations and enlightened manifestations through the agency of living mediums? If we can show that most of the reported phenomena of

Spiritualism can be explained by what we know of material conditions whilst we can also show that what we cannot explain is either unimportant, unprofitable, nothing but subjective assertion, the burden of proof that it is anything else lies with those who deny that it is unprofitable, unimportant and merely assertion, and as they never furnish the proofs there is no more reason to believe them than there is in believing in the existence of snakes and spectres in a room, because a man in an acute attack of delirium tremens says that they are there. I cannot find that in the treatment of mental disease there is any serious attempt to alter what are supposed to be such symptoms as are termed impaired Will and power of Attention, disordered Emotion, false ideas, obsessions, etc., by any other means than suggestion and material remedies. If we suppose, for sake of argument, a man whose affection for usual objects is lost or perverted, who cannot make up his mind, *i.e.*, who cannot will to do that which he desires, who cannot fix his attention, who cannot continue the good acts by which he was known, we may use the spiritual hypothesis, appeal to spiritual processes of which we have no knowledge and therefore do not know how to deal with; or whilst acknowledging the existence of a power which may have such inconceivable attributes, but only shows them when in conjunction with living material, we may try to bring about the correct interaction by righting the material. In the former case we are taking up the treatment of the Ecclesiastic; in the latter we act simply as medical men who find that in most cases the method of the Ecclesiastic or Spiritualist has no result, and that when there are favourable results, these may be explained by the material alteration induced, by suggestion, or by what is known as the personality of the operator, which is nothing more than an aggregate of physical properties.

There is neither time nor space here to enter into the discussion of the connection between the higher brain cells and ideas, but this much may be stated, that we do claim that education and experience do produce a wider range of mental function, and this is brought about by development of material structure (for we cannot educate an immaterial force which is supposed to be perfect), and therefore by providing a more elaborate material we can give more for the force to act upon, and if we find that such a function, as say Will, is absent, we can physically bring about such an excess of material in a special direction as may enable the force to act, *e.g.*, by suggesting to a person that he can do a certain thing we, by constant iteration, so impress certain cells of the "I can" order that the other opposing ones of the "I cannot" order lose their power through discontinuance of existing cause. In the same way he may grant that toxic agents or other causes of degeneration may prevent the power of response to Force, and that thus wrong and unbalanced action is brought about. In either case, whether we adopt the spiritual or the material view, the process resorted to is the same; we try to amend the material of which we know something, and we leave the spiritual, not because we evade its existence, but because we know nothing about it nor how to go to work upon it. The Spiritualists say that they can convert part of themselves into spirit form, leaving part behind into which they can re-enter. This part thus separated can enter into communion with other complete spirits of various degrees of superiority, or, as they express it, of different spheres. If it thus comes back with fresh knowledge, how does it impart it? It cannot, because the material which it re-enters is not educated to receive it; there is no available material for the new-informed spirit to work upon. Again, how can they separate this Force? If they can they must possess a controlling power over Force or Spirit which is all the time supposed to be the superior agent! After all, the educated material is necessary for the Spirit to work upon, and we may both ask the question and supply the answer. Why is nothing ever vouchsafed through an Idiot? Because the material for working upon is not there. It is in this way that they ascribe intellectual gifts to special

grants from spirit-land. They quote the case of George Stephenson, and say that the invention of the locomotive was put into his head by spiritual interference. We all know that the history of the discovery of the power of steam and the development of the engine is a very different thing from the implied spiritual influence of the Theocosmics, and that even now the machine is in a transition state and has not attained its full development. As to what becomes of the part of the body left behind and deserted by the exploring Spirit, we have no information, except that it does not vanish nor does it lose its life, though it evidently loses power of mental or nervous demonstration; anyhow, it must deteriorate. No wonder then that we have complaints of exhaustion after these spiritual communications, and the wonder is that if part of the Spirit can be separated and afterwards brought back with immunity, these Separatists do not disassociate the whole of their spiritual energy in a grand effort to extract more information; they may be leaving behind the very part which would be of real service to them! Wherever there is a supposed but unknown region, there are always plenty of would-be discoverers, and if, as the Spiritualists maintain, they are able to enter these regions and to return, we have a right to expect that there should be some result from this espionage; but so far they have brought back no grapes. The burden of proof that they have ever been into the coveted lands rests with the pioneers of the mission. There is a fascination in prosecuting search after the ideal to the neglect of the prosaic commonplace of the real. Even Tennyson walked miles to see the point on Lyme Cobb from which Jane Austen made her supposititious heroine, Louisa, jump.

One of the most neglected features in the study of psychological problems is that part which is called Epistemology, the realm of validity and reality. I see outside an external world which appears to me and to most others a reality of a certain and definite kind, but it is very possible that it is in essence of a very different nature from what it is conceived to be. As a fact, all thought should be received as the eccentric projection of what goes on as the result of stimuli and internal processes. When we see or hear an object or a sound, it is at a certain distance *outside* us, not at the very centres which receive the impression and internally have the perception of it. And so it is in thinking, in ideation, even in abstract ideas. If we think of abstract goodness or of concrete furniture or of the act of going upstairs, it is all *external* to ourselves, and in no way does it seem to be *within* us—the wonder indeed, is that, with an exoteric existence we ever come to think of *ourselves* as doing anything. A man sets himself to think of, or to do, certain things and they either happen or they do not, but in either case there is no consciousness of any internal process, all seems to be *outside*—even feelings of joy or sorrow are probably to be traced ultimately to the fact of Resistance, and are in no sense perceived as an internal change or state. After climbing to the top of what has been said to be an inaccessible mountain we may be satisfied and gratified and are said to feel pleased, but this is nothing more than the relief from the strain of certain *externalities*, the desire to be at the top of the mountain was an integral part of the idea of the mountain and the means and ways to be used in arriving there, the feeling of pleasure and pride in having succeeded are only the ideas of the congratulations of friends, of the downcast appearance of detractors, of the success either in fame or money of the book to be published, or of the applause of the learned society before which the adventure will be narrated, and all this is *external*; there is nothing more to be done, Resistance has vanished. I cannot but think that this externality, this consciousness of referring all that we do and think and say to what is *outside* has much to do with our views of the mystery of life. Eccentric projection has never been properly explained, and though it is certain that Presentations, Feelings, and Ideas are really within us, really, *i.e.*, in their actual material seat of resistance, yet the mystery is that we do not recognise them *where* they occur but only as outside ourselves—as if

indeed Mind was quite independent of Body. Hence the tendency to assume mysterious agency for what we notice, for that which we did not know we were ourselves thinking about. Very often the material structure of the brain takes action on its own account, in other words, energy is set loose in a manner foreign to the *res gesta*—accumulated energy is touched-off by some internal physical process, and the result is an induction or a deduction which surprises us, and inasmuch as it occurs in an unexpected manner, and is to all appearances external, the self-idea is apt to be cloaked in an externality which does not really exist, and what happens is referred to the influence of external agency. The *Deus ex machina* is no foreign god, it is oneself—the part of *themselves* which the Spiritists say they can convert into spirit form is the projected action of their own central mechanism—action which is possibly brought about by intense concentration on a limited area already well-primed with energy of a particular kind. Spectres and Ghosts are but the discharges of gorged centres accompanied with the well-known phenomena of eccentric projection, and Telepathy is an unauthorised and irrelevant conclusion arrived at by people who, recognising that what they think has a *deceptive externality*, but failing at the same time to perceive the illusion, invent to themselves the idea that they are voluntarily projecting waves of thought which may interact with other waves projected by individuals with whom they assert that they are in harmony. It seems to me that this fact of the eccentric projection of Mind or Thought has never been sufficiently appreciated in estimating the validity of reported demonstrations from the occult. That it is inexplicable does not prevent our acceptance of it as a fact, whilst it saves us from the uncomfortable and distracting suspicions that we are at the mercy of agencies which have been credited with powers and influences when all the time they are the unrecognised figures of ourselves—figures whose validity depends upon the way and extent to which we educate such receptive organs as we possess, and which, of course, it must be owned, are of greater or less development and potentiality in some than in others. If one reads the work of F. Myers, of Sir Oliver Lodge (The Survival of Man), and his account of Mrs. Piper, of telepathy and clairvoyance, one is bound to admit that some of the occurrences related by these imaginative (used in its speculative sense) and scientific men are inexplicable on the data vouchsafed, but the “cosmic scheme” spoken of, the “cosmic philosophy” of Myers is still undeveloped, and we who are anxiously waiting for something more than crudities, trivialities, and irregular and spasmodic utterances, are in the meantime brought face to face with contradictions of physical laws, which ought not to be the case in any scheme which professes to deal with that which, however immaterial it may be, is still acknowledged by its projectors to act in obedience to Law. We do not call the eminent men who have given in their adhesion to Spiritualism hard names, nor do we admit ourselves to be anything worse than sceptics who contend that our scepticism is quite ready to be turned into Belief when those upon whom the burden of proof lies have given us something more solid than assertion to found their edifice upon and have demonstrated the unity of law which is as binding upon a Creator as upon the created.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

A CASE OF A STRANGULATED HERNIA, FIRST IN ONE, AND THEN IN THE SECOND SAC (A HERNIA EN BISSAC) OF AN INGUINAL HERNIA.—MR. EDRED M. CORNER operated on a case of hernia.

Before the patient was brought to the operating theatre, Mr. Corner said that the patient was a man *æt.* 35 years, who was admitted three days ago with a strangulated inguinal hernia of the ordinary type. The man had no idea that he had a hernia until it suddenly appeared and was strangulated about twelve

hours before his admission to the hospital. He had never suffered from any pain or discomfort in that region. The first operation was a very ordinary one. The sac was found to contain little or no fluid and a knuckle of small bowel. After dividing the strangulating band, the neck of the sac, by a so-called herniotomy, the strangulated knuckle of bowel was drawn down and inspected, together with the portions actually pressed upon by the strangulating bands. Being healthy bowel, it was returned to the abdomen, when it did not recede, as returned bowel usually does. This was investigated, and a finger passed through the internal abdominal ring into the abdomen and the coils of small bowel in the pelvis. Hence all was deemed to be satisfactory, the hernial sac removed, the canal sutured and the operation concluded *secundum artem*. The first day after the operation the man was distinctly relieved. The second day the relief was not so satisfactory, whilst on the third day it was obvious that he either had intestinal obstruction or perforation. But, clinically, it did not appear possible that he could possibly have obstruction to the small intestine from the absence of clinical signs, *e.g.*, vomiting. Indeed, the great signs were severe abdominal pain, unsatisfactory action of the bowels, and that only to enemata, etc. In fact, in general unsatisfactory progress after the apparent relief of a strangulated hernia. He might have partial intestinal obstruction or peritonitis, probably connected with his strangulated hernia; possibly not. Hence, Mr. Corner said he was not going to reopen the patient's hernia wound, but was going to make a *cœliotomy* incision through the right rectus, so that he was in a position to explore the patient's hernial rings and his abdominal cavity, if necessary.

The abdomen was opened, and when the site of the strangulated hernia was examined it was found that a knuckle of small bowel entered and was strangulated in an abdominal sac. This abdominal sac was the intra-abdominal chamber of a hernia *en bissac*, the scrotal chamber having been removed at the first operation, and the strangulated bowel apparently, and unfortunately, reduced into the second and abdominal chamber, where it gradually became strangulated. Such an accident must be very rare.

Nothing much, Mr. Corner said, is known of these herniæ *en bissac*, probably because the second and abdominal chamber is overlooked, unless it becomes the site of a second strangulation, as in this patient, or discloses itself as a properitoneal hernia. These properitoneal hernia sacs are of two classes, prevesical, or in the iliac fossa. The former are much the most frequent. The latter, the iliac form, was present in this case.

The neck of the intra-abdominal sac was split by pressing a finger into it and the ensnared loop of the bowel released. The loop speedily recovered its colour and vascularity, becoming “returnable.” At one point where the bowel was pressed upon by the strangulating agent it was “doubtful” and was sequestered, *i.e.*, invaginated by a series of Lembert stitches with a continuous suture. The abdomen was closed. It was noticed that there was some degree of peritonitis present, and it was hoped that now that all strangulation was relieved the patient would recover from this.

SUBSEQUENT NOTE.—Unfortunately, the patient did not recover, a post-mortem examination showing that this was due to the extension of the peritonitis noticed at the second operation, and that the “doubtful” and sequestered segment of the bowel had not become gangrenous. This peritonitis had arisen from the diapedesis of organisms through the walls of the bowel just above the strangulation, and is an example of the infrequency of strangulated herniæ insisted on in the Erasmus Wilson Lectures of 1904, delivered before the Royal College of Surgeons.

THE importation of absinthe into the United States will be prohibited after October 1 next under a decision of the Pure Food Commission, which has been ratified by Mr. James Wilson, the Secretary for Agriculture.

SOME INTERESTING CASES FOR GYNÆCOLOGISTS.

At the Gynæcological Gesellschaft, Hr. Strassmann showed a patient, æt. 33, who had once been delivered with forceps, and twice spontaneously at later periods. The pelvis was a flattened, rachitic one, with a conjugate of 9½-9 cm. At the third confinement forceps had been applied; she was then given an anæsthetic and turning was performed. During this a rupture of the uterus took place. This was diagnosed at once, and laparotomy was performed, the patient being in a half-sitting position. In the abdomen was a living, full-time child, and a huge hæmatoma in the right broad ligament. Extirpation of the uterus was carried out, along with that of the so-called adnexa of the right side. The vermiform process also, which contained a coprolite, was removed. It was remarkable that the main stem of the uterine artery was uninjured. Recovery was uninterrupted, but after an interval of four weeks a uretero-vaginal fistula made its appearance. It was still there.

Hr. Sigwart showed a patient, æt. 36, who had given birth to nine children, all the labours being completed spontaneously and quickly. On this occasion the pains were weak, and they suddenly ceased altogether. The midwife recognised a transverse presentation. The elbow of the child was felt in the os uteri. Above the umbilicus, and to the right, was a hard tumour, the shape of the uterus; and to the left a similar hard body. Laparotomy was at once performed, when the fœtus was found to be totally expelled through a rent in the cervix. The main stem of the uterine artery was torn completely across; uninterrupted recovery took place after total extirpation of the uterus.

Hr. Dahlmann showed preparations from a woman, æt. 40, a 13-para., who had borne a full-time child nine times. She was in a febrile state when admitted. The membranes were ruptured at the end of two hours. Sudden and deep collapse and death after evacuation of the contents of the rectum. Cæsarean section was at once performed, and an asphyxiated full-time child extracted; artificial respiration was performed, but the infant died shortly afterwards. The post-mortem examination revealed a cervical rupture and retroperitoneal hæmatoma on the right side; there was a rupture also on the left. A microscopic examination revealed nothing. The attendants were therefore reduced to the conclusion that the defæcation was the ætiological factor.

Hr. Martin related particulars of the case of a 19-para. who had always had natural labours. On changing her into another bed, sudden collapse and death took place. It had been assumed that spontaneous rupture and fatal hæmorrhage were the cause of death, as nothing but a foot and part of the pelvis of the fœtus had been born.

Hr. S. Meyer showed preparations from a case of spontaneous labour in a case of myoma of the uterus. The patient had been delivered of a child, but hæmorrhage came on again shortly afterwards, the uterus still reaching to above the umbilicus three weeks after the birth of the child. Later on the hæmorrhage again returned, and the patient became jaundiced. The X-rays were applied, but in spite of this the bleeding came on again. Total extirpation by the abdominal route was performed, when a bleeding myoma, the size of the fœtal head, was removed. The Röntgen rays had completely failed in the case.

At the Verein Deutscher Laryngologen, Hr. Schmeden reported on 43 cases of

INFECTION OF HUMAN BEINGS BY FOOT AND MOUTH
DISEASE

through cattle. All the cases occurred last year, and in the Oldenburg district. The symptoms consisted

in a general febrile condition, with disturbances of digestion and the appearance of vesicles in the mouth, which soon ruptured. In some cases there were bullæ on the hands or feet. The cases, on the whole, ran a favourable course, but a fatal termination took place in one.

Hr. F. Siebenmann related a case of

INJURY TO THE HEAD AS THE CAUSE OF SIMULTANEOUS
PARALYSIS OF THE ŒSOPHAGUS, LARYNX AND NECK.

On inquiry into the literature of the subject, he had collected a total of nine cases in which there was a similar relation between the injury (fracture of the skull) and the symptoms. In three other cases recorded there was no paralysis of the neck. On consideration of the symptom-complex determined by Wiedmer and Reich, after severing of the vagus, he had come to the conclusion, taking into consideration the clinical course of his own cases, that Aveli's syndrome was caused by total and simple division of the vagus, and by that alone, but that the so-called Schmidt syndrome was set up by division of both the vagus and spinal accessory nerves. The accessory nerve, as it passed out from the head and into the jugular foramen, possessed only a motor function, and that only for the external skin muscles, the sterno-cleido and the cucullaris. The fact that in about one-half of the cases sensibility was retained on the paralysed side was explained by the further fact of the crossing over from one side to the other of the sense terminations of the sensory terminal fibres of the vagus. The same would be the case for the fibres for the special sense of taste of the glosso-pharyngeal.

AUSTRIA.

Vienna, Aug. 24th, 1912.

THE CIRCULATORY SYSTEM AND SALVARSAN.

DR. KARL WAGNER, of Graz, has observed peculiar pathological changes in the blood-vessels of two patients who died after Salvarsan injections, but not in consequence of these. (One died of pneumonia 3 months after the Salvarsan injection was made, the other died of typhoid fever 7 months after Salvarsan.) Meditating on these cases, Dr. Wagner came to the conclusion that knowing Salvarsan to be capable of producing inflammation in the muscles, when given intramuscularly, it would be absurd to assume that it would not damage the fine *intima* of the arteries. To confirm himself about the correctness of this assumption, he made experiments on animals (rabbits), and he actually found that Salvarsan causes inflammatory changes on the *intima* of all the pectoral and intestinal blood-vessels, the inflammation being noticeable even with the naked eye. In one of the rabbits he found an endocarditis (at some spots a verrucous one), the most attacked part of the *intima* being the *ossium atrioventriculare dextrum*. From these experiments he concludes, that (1) it is quite certain that Salvarsan acts harmfully upon the *intima* of the blood-vessels. (2) The degree of damage done depends upon the amount and concentration of the Salvarsan solution. (3) The usual dilution of Salvarsan suffices to prevent severe changes in the vessels, although thrombosis of one femoral vessel, and such like, have already been reported. (4) If changes can be found months after the injecting of Salvarsan, then the more rightly can we assume that several days after such injection the inflammatory changes are more pronounced. It is to be admitted that with the evacuation of Salvarsan from the organism, also when the reaction on the blood-vessels ceases, the inflammation diminishes in intensity.

NEW RADIUM INSTITUTE IN VIENNA.

The first Radium Institute—established for instructional purposes—has been recently opened here. For the time being the Institute is located in the court of the General Hospital (Allegemeine Krankenhaus). Radium carriers, small, round brass boxes, mounted with radium salts, are conveyed from here in various sizes and forms into the different clinics. Besides this, at the Institute radium emanation is produced in a

large quantity, and distributed among the sections of the hospital for curative purposes. The emanation is used in the form of drink, inhalation, and bath cures. Private practitioners may obtain radium salts from the Institute for a pay of 30 kronen (25 shillings) per half-day. The emanation is sold in drug stores at fixed prices. All the drug stores and hospitals, which use radium salts or emanation, stand under the control—as regards radium application—of the Royal and Imperial Radium Station. The station is under the management of Professor Riehl, the well-known dermatologist.

APPOINTMENTS.

The adjunct at the Serotherapeutic Institute in Vienna, Dr. Ernst Pick, has been appointed as extraordinary professor of applied medical chemistry.

Dr. Rudolf Matsenauer, extraordinary professor of dermatology and syphilography at the University of Graz, has been appointed as ordinary professor on the same subject.

DERMATITIS EXFOLIATA.

At the Gesellschaft für Innere Medizin, Zarfl reported that the child which he showed them a few weeks ago suffering from dermatitis had since died. This was a case of an infant with a peculiar history and irregular course of development. The affection commenced not with erythema as usual, but with a crop of "miliaria crystallina" which rapidly spread over the body raising up the epithelium. The child seems to have been infected by the mother, as her breast was covered with dermatitis and large pieces of the epidermis peeling off. Leiner thought at that meeting that the case was one of pemphigus neonatorum. In the discussion that followed Knöpfelmacher said he considered there was very little difference between pemphigus and epidermolysis to which he thought this belonged. Although the exudation under the skin commenced slowly it gradually increased, spreading extensively, but never forming the characteristic vesicles of pemphigus. In the whole course of the disease no vesicles appeared, but the cellular tissue below the skin had a fluctuating sensation.

TUBERCULOSIS.

Zarfl also showed another child, 6 weeks old, with congenital tuberculosis. When 17 days old the tubercular reaction was strongly marked with enlarged spleen and fever, which in the fourth week rose to a high degree, and in the groin and armpits the lymphatics were greatly enlarged, which reacted actively to the tuberculin injection. Pirquet considered this a case of congenital tuberculosis, but it was interesting that a child so young should respond so readily to the tuberculin reaction. Rach showed a girl, *æt.* 12½, with a subacute form of miliary tuberculosis, which, he said, demonstrated the cachectic type by the tuberculin reaction as the efflorescence was pale and slightly raised. The Röntgen rays revealed miliary deposit the size of hemp seed in both lungs which confirmed his diagnosis of miliary tuberculosis.

EXTRA-SYSTOLE.

Hecht exhibited a girl 7 years old with an extra systole of the heart and who suffered from a severe form of tuberculosis, the upper lobes in both lungs being affected and the cutaneous surface ulcerated. After a number of regular pulsations a pause occurred, followed by a strong contraction without a pulse wave, which he considered due to a detention in the periphery circulation or frustrated cardiac contraction. This extra systole may go on for years until a fever attack occurs or overstraining when it suddenly disappears.

PSEUDO-TETANUS.

Lüchler reported a case of pseudo-tetanus he had shown at a former meeting that was now comparatively well. All the muscles of the body with the exception of the diaphragm were in a perfect state of tonic contraction, the upper extremities and eyes sharing in the same fixed condition which lasted eight days, being only slightly relaxed during sleep. Throughout the whole

course the symptoms of genuine tetanus were not present as the reflex action was quite active and no history of traumatic neurosis could be obtained.

SWITZERLAND.

Berne, Aug. 24th, 1912.

INSURANCE AGAINST SICKNESS AND ACCIDENTS IN SWITZERLAND.

IN our neighbourland, Switzerland, insurance against sickness has been undertaken only heretofore by private concerns, while insurance against accident was the privilege of insurance companies. However, as this system has not stood the test of time, in 1890 the Government was obliged through the national vote to order the insurance of workmen according to a special law. The plan of the bill, however, was rejected, because it established compulsory insurance against sickness and accidents. The Government, therefore, had to elaborate a new bill, which entirely dispenses with compulsory insurance, and the proposal has been, so to say, unanimously accepted this year.

According to this new bill (*Bundesgesetz ueber die Kraken- und Unfallversicherung*), every Swiss citizen may become a member of the Sick Club, without regard to his income or means. There is no compulsory joining, but the law empowers the single cantons with the right of introducing in their own territory compulsory insurance, either for a certain class of people or for the whole population. The cantons may empower single villages or towns with such right. The administration of insurance is done by the former companies, and for their work they get State support. Switzerland, like England, is of the opinion that the State cannot restrict its activity merely on the making presents of paragraphs, but it must also bring pecuniary sacrifices too. This sacrifice amounts to 4½ to 5 million francs yearly, an enormous sum considering Switzerland's small revenue. The number of insured persons will amount to 800,000.

The insured persons are entitled to free medical attendance, free medicine, and at least one franc support in case of incapacity to work. This support cannot be given on more than 180 days a year.

As to the relation of doctors to the sick clubs, the law declares (in principle) the free-choice system, which permits the single clubs to make contracts with single doctors or medical associations, too. The bill is very liberal towards the medical men and chemists and instructs the clubs, that representatives of the clubs, together with the committees of medical and pharmaceutical associations, shall establish the rights and duties of doctors and chemists, and shall agree as to the lowest and highest medical fees, and the lowest and highest prices of drugs. In disciplinary or disputational questions an elected court shall decide. The bill has a very important paragraph; nominally it says that if from any reason no contract could be made with doctors or chemists, in that case the sick clubs are allowed, for at most one year, to endow the members with monetary compensation instead of medical attendance or drugs, respectively.

As to the insurance against accidents, this is carried on by the newly-to-be-established "*Schweizerische Unfallversicherungsanstalt*," in the directorate of which, probably, doctors too will be enlisted. The members incapacitated through accidents will be attended by the sick clubs, inasmuch as it does not last longer than 6 weeks, and for their service they get agent's premium, and get the quota of the State subvention.

UNITED STATES OF AMERICA.

New York, Aug. 18th, 1912.

NATIONAL PUBLIC HEALTH DEPARTMENT IN THE UNITED STATES.

FOR some time there has been a strong sentiment in the United States in favour of the establishment of a national public health service. Had it not been for the bitter opposition of those interested in proprietary

and patent medicines, who, owing to the possession of a very large amount of money, and who in consequence wield an immense amount of political influence, it seems more than likely that a national public health service would have been in existence ere now. By means of money judiciously expended a prejudice has been created to some extent against the medical profession, and the proposal has been stigmatised as a scheme to bring into being a "doctors' trust." However, in support of the plan are men of weight in all classes of society, and legislation to this effect will probably be introduced in the near future. In connection with this matter a Senate document on the subject of conservation of human life has been widely distributed recently by Senator Owen, of Oklahoma. The material for it was prepared by Professor Irving Fisher, of Yale, and Miss Emily Robbins, of New York, representing the Committee of One Hundred on National Health. The statistics and statements in this document go to show that the annual financial loss to the United States by its failure to properly conserve human life amounts to \$3,000,000,000 (£600,000,000). Acute diseases are held responsible for a considerable part of this loss, while to chronic diseases is attributed the greater part of the waste of life, and, moreover, these are said to be increasing. Minor ailments, for the most part thought to be preventable, are at the present time costing the nation very large sums, owing to the incapacitation of persons thereby and through leading to serious illness. Industrial accidents, also largely preventable, are exacting a heavy annual toll. It is asserted that the only effective manner in which this wastage of life, with its national economic consequences, can be modified is by national action.

The following are some of the reasons advanced in support of the proposal to establish a great national department of health. The work of the department would be varied, and would include direct work in promoting health on the part of the Government, such as administering the Food and Drug Act, aiding the healing and educational agencies, both city and State, obtaining information concerning the cause and prevention of disease, and disseminating scientific information on all health subjects. Many startling statements are set forth in the document, which is, of course, designed to arouse public interest in the question. For instance, Dr. Charles Wardell Stiles, of the Public Health and Marine Hospital Service, declares that the United States is seven times more dirty than Germany, and ten times more so than Switzerland. He asserts that lack of interest in preventive measures against disease is slaughtering the human race. He takes the stand that race suicide is not so great a menace as race slaughter, and that it is rather a case of too many children being allowed to die than of enough children not being born. It is estimated that tuberculosis alone costs the United States \$1,000,000,000 (£200,000,000) annually; while Dr. George M. Kober estimates that typhoid fever causes the nation a financial loss of \$300,000,000 (£60,000,000) a year. With regard to acute diseases, this statement is made: "The loss from tuberculosis has been reduced to half of what it was thirty years ago. Nevertheless, of the 90,000,000 people now living in the United States, at least 5,000,000 will be lost through this disease because adequate effort is not put forth to prevent it. Besides the economic waste through deaths from any disease, the waste through sickness of the same disease is also colossal."

Further statements are as follow. Great as are the reductions of the rates of infant mortality by means of improved milk and water supplies and by educational campaigns, the rate is still enormous. While the death rates from acute diseases have been greatly reduced, the rates from chronic diseases have been increasing steadily. Cancer is one of the chronic diseases apparently on the increase. Finally, the assertion is made that the annual death roll and the 3,000,000 constant sick beds could be reduced by one-fourth to one-half by the institution of proper measures. It is to be hoped that the widespread dis-

tribution of such facts may have the effect desired, although it must be granted that those opposed to national control of the health service are very powerful, and will use every effort to prevent legislation that will clash with their interests. It may be observed that the very excellent U.S. Public Health and Marine Hospital Service now fulfils many of the functions of a national health department. Indeed, some of the medical journals, prominent among these being the *Medical Record*, urge that the scope of service of this capable body of men should be enlarged, and a public health department created in this fashion.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

THE INSURANCE ACT.—A meeting representative of the medical practitioners of Co. Tyrone was held in Omagh last week, Dr. E. C. Thompson presiding. A resolution pledging those present to adhere to the resolutions of the Conjoint Committee in Dublin was proposed by Dr. Lyle (Newtownstewart), seconded by Dr. Burgess (Coagh), and passed unanimously. The Local Medical Committee of County Antrim met at Ballymena on the 16th inst., Dr. A. D'Evelyn, J.P., presiding. Dr. Gawn, J.P. (Antrim), was appointed vice-chairman, and Dr. Davison (Ballymena), honorary secretary. It was decided to enlarge the Committee so as to include all those in active practice in the county, and to appoint an executive committee of six representatives from the six unions of the county, with the chairman, deputy-chairman and honorary secretary. In connection with the appointment of a superintendent tuberculosis medical officer for the county, the Committee have informed the County Council of their objection to the scheme proposed, the salary not being sufficient to attract a good man, and the work (including attendance at ten or eleven scattered dispensaries) more than any one man could do efficiently. At a meeting of the County Monaghan Health Insurance Committee held on the 21st August, an important question was raised as to whether sanatorium benefits could be bestowed on persons who were not insured. It was pointed out that the large majority of householders in the county were small farmers, who would not be insured. The Local Government Board was interrogated upon this point and replied that under the Act of 1908, all inhabitants of the county could be treated. As this Act is not in force in Co. Monaghan, steps were at once taken to bring it into force.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE BRITISH POPULATION QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your leader of to-day, August 21st, on "The French Population Question" ends with the following sentence: "The result of the enquiry by the new Commission cannot be without importance to the people of these islands, seeing that our present falling birth-rate, if continued, will bring us within a very few years into a position exactly similar to that of our neighbours." This statement gains point and emphasis from the Registrar-General's Annual Summary, which also is published to-day. The birth-rate in England and Wales, having fallen steadily for years, has been during 1911 the lowest ever recorded. The cause is the same as that in France—married couples are more and more declining the burden and responsibility of child-rearing. We are now within a measurable time-distance of a numerically stationary population. It seems evident that what you rightly style "a gigantic system of artificial selection" is pretty certain to

evolve an inferior stock unless based upon true prudence and guided by exact science. It seems also evident that unless these islands can go on producing an exuberant population, equal physically, mentally, and ethically to the best among civilised peoples, our competitors for the dominion of the world, the British Empire is doomed to destruction. The Prime Minister of New South Wales, in a speech a year or two ago, declared that unless they could fill their lands with people of their own blood, they would not for long be able to call Australia their own. Australasia is as big as Europe. Including New Zealand, it contains less than 6,000,000 inhabitants. With a properly organised imperial system of emigration this Dominion alone could easily receive and absorb the whole of our normal increase, say, about 500,000 annually. But besides Australasia we have Canada, Africa, equal to about two more Europes, not to speak of the West India Islands, and other vast domains, tropical or sub-tropical, which, with the extinction of their special climatic diseases, are becoming more and more fitted, especially in their highlands, for people of European blood. If neo-Malthusianism led to improvement in the breed the harm would be no doubt lessened, but it would be easy to show that this cannot be the result so long as the system is carried on regardless of science, and with no consideration save what is based upon the narrowest form of egoism.

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

August 21st.

A DOCTOR'S WIFE ON SECRET DRINKING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your manager can tell you that my husband is among your oldest subscribers, but neither he nor you can be aware that I am one of your most constant readers. During all the years I have been on terms of friendship with considerable numbers of patients, and although I resist the temptation to write, I have often the opportunity of viewing matters from behind the scenes of domestic life which, if described, might not be without value to many family practitioners. In your leader this week on "Alcohol and Tobacco," I was struck by the fact that you do not even allude to the question of secret drinking among women, nor refer to the facility for this vice that is afforded by the alcoholic "tonics" now so widely advertised. My attention has been recently more closely directed to this question by the work and writings of Dr. Mary Sturge, of this city. Reports of her speeches have been published, and her evidence a few weeks ago before the Select Committee on Patent Medicines was also summarised in some daily papers. I can vouch for the fact that these alcoholic mixtures are in great demand and constant use among the wealthier class of women, who are sinking or have already sunk to the level of the confirmed inebriate. These women are mostly ashamed of their vice, and are able to clothe it from husband, children and servants by taking the supply of drink under the guise of a tonic. On the other hand many simple women are taking these pernicious compounds, and administering them to their children, without the least suspicion of the harm they are doing. It seems to me that if there are no other secret remedies the sale of which calls for regulation by Government the class to which I refer do, at an early rate, urgently demand attention by Parliament. I enclose my card and am,

Sir, yours truly,

A DOCTOR'S WIFE.

Birmingham, August 23rd.

TURKISH BATHS AND THE SHOPS ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to the reference in your current issue to the conditions of employment of Turkish Bath attendants; you appear to think that they are a body of rather ill-treated men and women, and

that their circumstances call for some amelioration on the lines of a recent Act of Parliament. I cannot of course speak for the Baths other than those under my control, but I believe the conditions obtaining in our establishments are practically similar to those in vogue throughout the trade. Our shampooers and cooling-room attendants have for years enjoyed greater relaxation than would be accorded if the Act were put into force and they have many other privileges with which it does not seem necessary to trouble you.

Their occupation is as you admit, a healthy one, and though their hours of duty if compared with those of some of the constructive trades would appear to be long, if they are contrasted with the ordinary hours of a shop assistant they are the reverse. Our people earn a very liberal remuneration, they are quite happy and comfortable in their employment.

I am, Sir, Yours faithfully,

TURKISH BATH MANAGER.

[We are glad to publish our correspondent's letter and to learn that the conditions of employees in the establishments under the control of one company, at any rate, are satisfactory.—ED. M.P. and C.]

ADVERTISING THE INSURANCE ACT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having had leaflets innumerable explaining the supposed benefits which the worker will derive from the Insurance Act—which, by the way, is rather a contradiction of the statement frequently made that the workers were crying aloud for the benefits which will result from the Insurance Act—and now that they have obtained that for which they so ardently wished, explanation of what they desired is necessary! We have "a poster" illustrative of maternity benefits, with inset some of the great benefits of this scheme. Among these I notice free medical attendance and medicine for life. I have only one question to ask, which is, "Is this honest?" If so, I should like to hear the definition of honesty of the persons responsible for this poster. There may be a lull in the storm pending the report of the Insurance Commissioners, but of one fact we are certain, that unless our cardinal points be granted, the Act, so far as medical benefits are concerned, will be as unprolific as the barren fig tree. Possibly those responsible for this poster are taking as their motto, "Let us eat, drink, and be merry, for to-morrow we die."

I am, Sir, yours truly,

(S. J. ROSS.)

Monkhams, Bedford, August 25, 1912

OBITUARY.

...of medical and surgical science and the amelioration of human suffer-

ing. He gave freely of his time and service to the great work of the hospitals, and was the pioneer of many reforms in the practice and methods of obstetrics generally. He contributed many valuable papers to the medical journals, and wrote a number of treatises of value to the profession. With Dr. James Niven, the Manchester Medical Officer of Health, he succeeded in launching the "Medical Chronicle," and later he undertook the larger enterprise of establishing the "Journal of Obstetrics and Gynaecology of the British Empire," with the management and editorial conduct of which he was long associated. Despite the demands of his professional calling Sir William Sinclair took an active interest in the political as well as the municipal life of Manchester. Up to 1886 he was a staunch Liberal, but, like so many others, he then revolted against Mr. Gladstone's surrender on the Home Rule question. He became a Liberal Unionist, and for nearly twenty years was chairman of the South Manchester Liberal Unionist Association. He took a keen interest in the municipal life of the city, and for four years, from 1893 to 1897, served on the City Council as a representative of St. Luke's Ward. Sir William, who was knighted in 1904, married in 1883 a daughter of Mr. Andrew Haddon, of Denholm, and they had two daughters.

MR. WILLIAM CLAPTON, OF CANTERBURY.

WE regret to announce the death of Mr. William Clapton, F.R.C.S., formerly of 30, Queen Street, E.C., which took place on the 20th inst., at Rose Villa, St. Stephen's Road, Canterbury, at the age of 78. The deceased, who was educated at Christ's Hospital, received his medical training at St. Thomas's Hospital, which was then at London Bridge, where his elder brother, Dr. Edward Clapton, had preceded him. After a successful career as a student he entered upon practice in the City of London. For ten years he represented the Vintry Ward on the Court of Common Council, retiring in December, 1882. He was medical officer of the British Equitable Assurance Company, and held other important appointments. On his retirement from practice he settled at Canterbury, where he devoted himself to social and philanthropic work, in connection with the Church and with various societies and charities.

MR. E. JONES, OF LITTLE BURSTED.

By the death of Mr. Edgar Jones, J.P., M.R.C.S., which has taken place at his residence, The Elms, Little Burstled, Essex, the medical profession has been deprived of its oldest member. Mr. Jones, who was also the oldest Justice of the Peace, was in his 103rd year. He was a native of Somersetshire, and was born in 1810. He became M.R.C.S.Eng., in 1834. For many years he was Chairman of the Billericay Bench. He was formerly engaged in medical practice in

a long-lived family. His father died at the age of 91, and his eldest brother at 90. His sister lived to be almost a centenarian, and he has a brother still living, who is over 90.

SPECIAL ARTICLE.

TROPICAL DISEASES IN NORTHERN AUSTRALIA.

THE existence of tropical diseases in Northern Australia has been somewhat minimised in the past, but expert investigation has recently shown that these diseases, though rare on the whole, cannot be ignored. The Preliminary Scientific Expedition to the district has recently issued a report to the Commonwealth Government from which it is evident that a necessary condition of effective white occupation must be the introduction of medical officers who are thoroughly trained in a knowledge of tropical diseases. As Dr. Breinl, the Director of the Australian Institute of Tropical Medicine, points out, "the number of deaths due to 'fever,' in most instances malarial fever, has been most high throughout." In 1909 and 1910 malaria accounted for 26.47 and 20 per cent, respectively of the total death rate. Dysentery also accounts for a certain number of deaths nearly every year, and in certain years epidemics have made their appearance and there has been an increased mortality on that account. Other diseases, such as beri-beri, ankylostomiasis, yaws, trachoma, and leprosy are not unknown, but so far the cases have been for the most part sporadic.

The most interesting feature of the report from the medical standpoint is the fact that the evidence contained tends to show conclusively that effective white settlement is primarily a medical problem. Despite the tropical climate those residents and their children who care to live a reasonable life, taking adequate exercise, enjoy good health. As yet there is little, if any, evidence of the effect of the climate on a third generation, and it would be necessary to take this generation into consideration before a dogmatic statement on the subject could be made. Dr. Breinl says that life on the stations is ideal from a health point of view. The active and mainly outdoor life, the comparatively cool and dry winter, as experienced on the tablelands, are all conducive to splendid physical development and robust constitutions, granted that malaria, alcoholism, and other such deteriorating influences be avoided. During the short time that the expedition was in the district, however, they found that the most elementary precautions are not taken against the spread of malaria. The conditions in the mining settlements are such that it would prove a comparatively simple matter effectively to eliminate malaria by the recognised method of kerosining their breeding places, or by removing the mining camps from the rivers where such treatment is not economically practicable. The problem of tropical diseases, however, is a wider one than the extirpation of malaria. The conditions in the Northern Territory are such, geographically, as to expose the district to the danger of infection from the Dutch East Indies, and from China, and with the elementary sanitary arrangements that at present exist, tropical diseases, if once introduced, might easily give rise to serious epidemics. To guard against this it seems desirable that an extensive study should be made of the diseases prevalent on the lesser-known islands with a view of framing adequate Quarantine laws. That the risk is a real one is shown by the fact that one or two species of mosquitoes belonging to a genus prevalent in the East and Malay States have been found in the Northern Territory, which seems to indicate that an introduction of insects from the East has already taken place.

DR. E. FAIRFIELD THOMAS has been appointed Tuberculosis Medical Officer to the Wrexham Tuberculosis Dispensary for the counties of Denbigh and Flint, in connection with the Welsh National Memorial Association.

never smoked or took
last few years he had been perfectly normal in his diet, taking all the plain, healthy foods which came readily to an old Essex farmstead. Mr. Jones came of

REVIEWS OF BOOKS.

ACHRONDROPLASIA. (a)

THIS suggestive book, which contains a short introduction by Prof. Elliot Smith, deals with the skeletal peculiarities of the achondroplast, and endeavours to offer an explanation as to their causation. The monograph consists, in part, of the author's observations on the skeletons of two dwarfs which have come into his possession, but he also refers to the somewhat scanty literature on the subject, and particularly to Kaufmann's work.

The disease may leave some cartilage formations untouched, and may even, in a minor degree, affect some membrane-formed bones, so that neither chondrodystrophia nor achondroplasia, as a name, fully describes it.

Having considered the bones of the limbs, trunk, and particularly those of the skull, Dr. Jansen concludes that the disease commences between the second and ninth weeks of foetal life. He states that the pituitary body is only markedly affected in unviable cases. Particular stress is laid on the changes in the region of the oral and nasal cavities, and more especially on the inward curving of the alveoli, the narrowing of the choanæ and the increase in the angle between the hard palate and the basis cranii. To the latter two factors he attributes the noisy bubbling respiration often met with. The dorso-lumbar kyphosis he regards as constant, and attributes it and the changes in the nasal and oral chambers to the effects of mechanical pressure.

Dr. Jansen endeavours to prove that the cause of this rare affection is mechanical pressure exerted by the amniotic fluid, producing infolding of the foetus and general ischæmia at a time when the cartilage is growing rapidly and requires more food than the other tissues. It, therefore, suffers most, and never recovers fully from the temporary setback; it is the later cartilage-formed parts which suffer most.

The book concludes with a consideration of the effects of pressure in causing some minor defects which may be found in association with achondroplasia. The writer's theory is ingenious, and it will be interesting to see how far it is supported by further work. The book is excellently turned out and contains some good illustrations.

THE SURGERY OF THE HAND. (b)

THOSE surgeons who are familiar with the series of articles on the hand and its infections which have been published during the last seven years by Dr. Kanavel will require nothing more than the announcement of the publication of this volume to make them obtain it immediately. It is certainly the most noteworthy work on this subject that has appeared in recent years. Every surgeon is familiar with the immediate disaster and the permanent disability which too often follow the ordinary text-book treatment of septic processes in the hand. Those books usually at the command of the general practitioner treat infections of the hand with a brevity utterly out of proportion to their importance. Dr. Kanavel, with due regard to proportion, gives in detail essential anatomical points which are not dealt with in anatomical books. He then describes the pathological processes in this region, and finally, in the sections worthy of highest praise, describes the exact treatment for each variety of infection in each special site. We commend the author for clearness of expression, even when it is at the expense of repetition. The methods by which he arrives at his conclusions

(b) "Infections of the Hand. A Guide to the Surgical Treatment of Acute and Chronic Suppurative Processes in the Fingers, Hand and Forearm." By Allen B. Kanavel, M.D., Assistant Professor of Surgery, North-Western University Medical School; Surgeon, Wesley and Post-Graduate Hospitals, Chicago. Pp. 447. Illustrated with 133 Engravings. London: Baillière, Tindall and Cox. 1912.

are described, and greatly add to the scientific value of the work. It is seldom that we can give such unalloyed praise to a book, but this is a volume which every practitioner should possess and which no surgeon could read without profit.

SURFACE ANATOMY. (a)

THE present edition is really a reprint of the fourth one, which we reviewed some time ago. Many of the illustrations, however, have been improved, and in some a judicious use of colour is made, this throwing the parts, especially the arteries, more into prominence. The illustrations are now very good, and give the student a clear idea of the relative position to the surface of the underlying parts. The subject matter is concise, but yet sufficiently full for ordinary use. We can heartily recommend the present edition as one of the best books of its kind for students' use.

THE TREATMENT OF SHORTSIGHT. (b)

DR. LINDSAY JOHNSON is to be thanked for making available to English-speaking medical men in their own tongue the short but extremely important monograph by Professor Hirschberg on the Treatment of Shortsight. The book runs to 120 pages only, but it affords space for some discussion of the ætiology and prognosis, as well as the treatment of shortsight. The statistics of his own cases make the author's right to speak with authority quite clear, if there were any doubt on the point; his experience is simply enormous.

Professor Hirschberg's views on the prescribing of glasses frequently differ from those commonly taught in English schools. He is very sceptical about the existence of accommodative spasm. In low grades of myopia, between 0.75 and 3D, he gives full correcting glasses for constant wear; in medium degrees, from 3.5 to 6D, entirely or nearly correcting glasses, are given for distance, and weak glasses or none at all for near work. In higher grades, 6D and upwards, two pairs should always be given, one for distance, not more than 8 or 9D generally, and another pair for near work, about half as strong, or a little more. In cases of very high myopia, stronger glasses than 9D may be given in a lorgnette for occasional use, not to be worn constantly.

The changes in the media and fundus of the myopic eye are very fully described, as is the seldom-mentioned subject of myopic glaucoma. That frequent complication of high myopia, detachment of the retina, is discussed at length, and the author's dictum is:—"The facts speak loud and clearly, the theories are debatable, the treatment risky, the cure rare." Very early recognition and treatment by rest offer, he thinks, the only real hope of cure.

Treatment of shortsight by removal of the lens does not much commend itself to the author, and he seems to have given it up, in spite of some very good results. In any case it is only to be considered in specially favourable cases with over 15D of myopia.

Professor Hirschberg is strong on the point that no school child should wear spectacles unless prescribed by a doctor.

A few misprints may be pointed out:—p. 24 "revolution" should read "resolution"; p. 45 "for the worst" should read "for the worse"; p. 49 "by" is used instead of "with," and the sentence "Many surgeons etc.," is split in two; p. 96 "almost" should read "at most." One wonders why a book translated by an English surgeon and published in London should offend us with such words as labors, hemorrhage, macula region (for macular region), but probably "Printed in U.S.A." accounts for this. These, however, are small blemishes, and one must congratulate

(b) "The Treatment of Shortsight." By Professor Dr. J. Hirschberg, Berlin. Translated by G. Lindsay Johnson, M.D., F.R.C.S. London: Rebman, Ltd.

author and translator on one of the most interesting and useful ophthalmic books that has appeared for years. No ophthalmic surgeon unless he has reached the age when his views and methods are rigidly fixed, can afford to neglect a study of it, and few will study it without pleasure and profit.

OPHTHALMOLOGY. (a)

THE first volume of a textbook of ophthalmology in the form of clinical lectures by Professor Roemer of Greifswald, translated by Dr. Foster of New York, is an interesting book, specially to those engaged in clinical teaching. It is an attempt to discuss eye diseases as in the clinic; the idea is to give a definite clinical picture of a disease, and then discuss its variations. This first volume contains 275 large pages closely printed, but owing to the colloquial and diffuse style, there is not so much matter in it as one would expect. There is a great amount of repetition, and yet many important points are entirely omitted. For instance, four pages are given to the treatment only of phlyctenular ophthalmia, and four to diabetic cataract, and on the other hand, in discussing cataract operations generally, no mention is made of irrigation, and Colonel Smith's operation is only mentioned in a translator's footnote. The superficial diseases receive the more detailed consideration all through. No less than nine types of corneal ulcer are described: the account of pneumococcal ulcer is excellent, as is also the lecture on corneal opacities resulting from ulcer and other causes, but the names are rather trying. Phlyctenular ophthalmia is called *keratoconjunctivitis eczematosa*; it is attributed to the habitus scrofulosis, and that again is discussed under two forms, the torpid and erethistic types. As regards the important part played by the translator, he seems to have been over-anxious to be literal, and to include everything. A discussion on the relative merits of the North Sea and the Baltic for sea bathing is rather futile in a book for English and American readers, and references to the Austrian pharmacopœia without a note as to the drugs mentioned, seem out of place. But our chief complaint is the treatment meted out to the Anglo-Saxon tongue. What can one say of a man who, wishing to say that the retina is healthy, says its "functionates normally"? As we have said before, American authors should be compelled to undergo a preliminary training in reading the Bible and Shakespeare, to prevent such atrocities. On the whole, the book is worth study by teachers, but it is unsuitable for students, and will not take the place of the ordinary systematic manual. The illustrations, specially the coloured plates, are excellent.

SURGICAL OPERATIONS. (b)

THIS volume, which is somewhat more than a handbook, gives a very concise and accurate *résumé* of modern German surgical teaching. In fact, we would prefer the author to give more details of his own procedure and *technique* rather than to describe the operations as performed by other surgeons. In a moderate space the conciseness of the author has made it possible to give the essential details of a large number of operations with greater completeness than in the ordinary text-book. We are glad to see that the complications of anaesthetics are clearly described and the necessary measures for relief indicated. The *technique* of lumbar puncture and the administration of spinal anaesthesia is adequately dealt with. The chapter on thoracic operations is good, as it shows what has been done in the operative surgery of this

region, though it sometimes leaves us in doubt of how to do it. The introductory chapter deals with anti-sepsis and anaesthesia, and the following sections with the blood-vessels, the extremities, the head, neck and chest, the abdomen and the genito-urinary organs. The illustrations and diagrams are very useful, and many things are figured which are not usually thought worthy of a picture, but which increase the usefulness of any text-book to a very great extent. The translation, as well as the spelling, might have been better, but the book as a whole accomplishes its object as an excellent handbook for students and practitioners.

OPERATIVE MIDWIFERY. (a)

WE are satisfied that Dr. Davis, well seconded by his publishers, has produced a work which will live and give pleasure to many obstetricians. After a general introduction, the volume is divided into four parts, the first on the Surgery of Pregnancy, the second on the Surgery of Labour, the third on the Surgery of the Puerperal period, while the concluding part is a treatise on the Surgery of the New-born.

The text has been compiled with great care. Each subject of operative interest is included and explained. There is no padding, and the operations in general use as well as those which have been more recently evolved are made easy for those who have not had the good fortune to witness or perform them. The illustrations are excellent, and the author is no doubt wise in including many of the best illustrations from other text-books. More than one hundred are taken from the works of Bumm and Dr. Munro Kerr. Regarding the latter, we must feel a certain amount of elation on finding the illustrations from a British author's work in an American text-book; far more often is this compliment reversed. The beautiful series of pictures on Ectopic Gestation which accompanied Ladinski's monograph on the subject in the *American Journal of Obstetrics* is placed before us. The bibliography is excellent, and we cannot imagine a more thorough reference index for the writer on subjects of obstetrical interest. For this alone, apart from its other fine properties, Davis's "Operative Obstetrics" should find a resting-place in the library of every obstetrician.

TUBERCULIN TREATMENT. (b)

IN the new preface to the English edition of this work, the author states that the great need of many practitioners is a "sufficiently intimate knowledge of the complicated factors concerned in the cure of tuberculosis and the action of tuberculin, as they often assume that these are simple immunising actions. From such a shallow study there results not only bad choice of cases for tuberculin treatment and faulty *technique*, but also a lack of accuracy in judging the results. This lack of judgment can never be supplied by statistics and leads to aimless and unscientific experimenting with all possible kinds of tuberculin, resulting only in false conclusions." The reader will find here a succinct account of the mode of action of tuberculin in general and the principles of tuberculin-therapy. Dr. Sahli has chosen Beraneck's tuberculin for discussion throughout, but the broad outlines of the treatment hold *mutatis mutandis* for all tuberculins. The first portion of this instructive handbook deals with the practical part of the subject, and we notice that the author believes strongly in the value of tuberculin in the initial, afebrile cases of tuberculosis. The great advantage of the treatment at this stage is that all the signs of improvement, etc., can be noted and checked while the patient is still pursuing his ordinary

(a) "Operative Obstetrics, including the Surgery of the New-born." By Edward P. Davis, A.M., M.D., Professor of Obstetrics, Jefferson Medical College, etc., etc. Pp. 483, with 264 illustrations. Philadelphia: W. B. Saunders Company. 1911.

(b) "Tuberculin Treatment." By Dr. Hermann Sahli, Professor of Medicine in the University of Berne. Translated from the Third German Edition by W. B. Christopherson, with an Introductory Note by Dr. Egbert Morland, M.B. and B.Sc. Lond., M.D. Berne. Pp. 198. London: John Bale, Sons and Danielsson, Ltd. 1912.

(a) "Text-book of Ophthalmology in the form of Clinical Lectures." By Dr. Paul Roemer, Professor of Ophthalmology at Greifswald. Translated by Dr. Matthias Lanckton Foster, Member of the American Ophthalmological Society. Vol. I., illustrated. Rebman, Ltd. 1912.

(b) "Surgical Operations. A Handbook for Students and Practitioners." By Prof. Friedrich Pels-Leusden, of Berlin. Translated by Foxton E. Gardner, M.D., of New York. Pp. 726. Illustrated. London: Rebman, Ltd. Price 30s.

avocation. Herein, then, lies the scope of the tuberculin dispensary. Mixed infections, it is stated, are often erroneously made the scapegoat for the imperfections of the treatment, whereas the causes of failure are rather to be sought in the absence of the natural healing factors, inability to obtain "tox-immunity," and last, but not least, an incorrect *technique*. The use of focal reactions is defended upon the ground that this method produces a local inflammatory action of the lysinised tuberculin which differs from the means of producing inflammation once employed, such as chloride of zinc, hetol, etc., in local tuberculosis, in that the tuberculin stimulates just those specific elements of the inflammatory anti-action which are essential for the cure of the disease.

The second portion of the book deals with the theory of the nature and action of tuberculin, of immunity to tuberculosis and the cure of tuberculous infection. Numerous arguments are given in support of the Wolff-Eisner theory of tuberculin action, the essence of which lies in the assumed existence in tuberculosis of an antibody of the nature of an amboceptor. According to this view, the cause of tuberculin reactions and local and general damage in tubercular infections is not the tuberculin itself, but, as Wolff-Eisner describes it, a secondary decomposition-product formed from the tuberculin by the action of a lytic antibody. A full bibliography is given at the end of this useful work which we can cordially recommend to all desirous of becoming acquainted with the methods of tuberculin therapy. A word of praise is due to the excellent manner in which the German idiom has been rendered intelligible to English readers.

MEDICAL NEWS IN BRIEF.

The Sixth International Congress of Midwifery and Gynaecology

Will be held in Berlin from the 9th to the 13th of September under the patronage of the Empress of Germany. Professor E. Bumm, Geh. Med. Rat. of the Charité Hospital, is President. On Monday, September 9th, the Congress opens with a meeting of the Organisation Committee, to be followed by a Festival Inauguration in the House of Parliament, when addresses from the Representatives of the Government, the Public Authorities, and the Delegates, will be given. In the evening there will be a reception in the garden of the House of Parliament, given by the German Obstetrical Society. On the following day the first and most important discussion will commence, on the "Treatment of Wounds of the Peritoneum," when the various Referees will deliver their reports, and several papers will be read. The same evening there will be a reception of the Congress by the President. On the Wednesday the discussion will be continued and that on the second subject, the "Surgical Treatment of Uterine Bleeding during Pregnancy, Delivery and Childbed," will be opened. That evening a reception will be held by the city of Berlin in the Town Hall. Thursday will be devoted to individual communications, and on Friday there will be various demonstrations by different members of the Congress at the Charité Hospital. Each morning there will be operations in the different clinics, to which all members of the Congress are invited. Dr. E. Martin, Artillerie Strasse 18, is the General Secretary.

Messrs. Thos. Cook and Son have issued a special Itinerary for British members of Congress to and from Berlin.

The Opium Question in India.

It is reported that the Government of India have notified important changes in their internal opium policy, especially in connection with smoking and the preparation of smoking material, both of which they invite the provincial Governments, including Burma, to prohibit absolutely by legal enactment when practised in saloons or gatherings numbering more than two persons.

The Government negative the proposal to prohibit individuals from smoking as being at present impossible, and involving inquisitorial methods, but they propose to reduce the amount of opium which an individual may lawfully possess, and to increase the price of opium sold by the Government with a view to discouraging all classes from the consumption of the drug. The rules for the sale of morphia and allied opium compounds are also revised with a similar object.

Hospital Treatment for Soldiers' Wives.

UNDER War Office authority arrangements have been made for the admittance to St. Thomas's Hospital of the wives and children of soldiers on the married establishment serving in the London district. No charge will fall on the soldier in respect of this arrangement, but only cases in actual need of operation, skilled nursing, or hospital treatment generally will be admitted.

Medical Service in the Highlands.

THE Highlands and Islands Committee appointed by the Treasury to inquire into the adequacy of medical service in the Highlands opened its sittings in Inverness last week. Sir John A. Dewar, M.P., chairman, presided, and the other members present were the Marchioness of Tullibardine, Mr. J. Cullen Grierson, Mr. Andrew Lindsay, Dr. McVail, Dr. Miller, Dr. Leslie Mackenzie, Dr. J. L. Robertson, and Mr. Beaton, secretary. Evidence was given by representatives of the medical profession, including the medical officers of health for Inverness-shire and Ross and Cromarty, and by medical practitioners from certain of the more sparsely peopled parishes to the eastward of Inverness-shire and Ross-shire. Several of the witnesses who had long experience of country practice were able to give the Committee valuable evidence as regards the difficulties and expense of travel and the disability of many people in the poorer parts to pay fees in any way adequate to the expenditure of time and money in providing even a very modified medical attendance, and the consequent disinclination on the part of the poor but proud to call in a doctor except in the extremest cases, and often when it was too late.

The supply of doctors, nurses, and hospitals and means of communication by telephone and otherwise, and travelling facilities, and the position of the parish medical officer as regards income, residence, and security of tenure were among the subjects discussed as bearing upon the adequacy of the existing medical service. To-day and to-morrow witnesses representative of public authorities and witnesses from the general public resident in the outlying parts in the eastern portions of Inverness-shire and Ross-shire will give evidence.

The Guild of St. Luke for Medical Men.

THE annual service of the Guild of St. Luke will be held at St. Paul's Cathedral on the evening of Tuesday, October 22nd. The preacher will be the Bishop of Stepney, who is a son of the late Sir James Paget, the well-known surgeon. The Lord Mayor, Sir Thomas Crosby, M.D., will attend with the Sheriffs in State

Medical Men and the Territorial Force.

At a meeting of the Cardiganshire Provisional Medical Committee held at Lampeter last week, Dr. J. Powell, Newcastle-under-Lyme, presiding, it was unanimously resolved to support the movement that all medical practitioners acting as medical officers to the Territorial Force be called upon to resign their commission. It was strongly felt that as the State through its Ministers intends to work the Insurance Medical Benefit in such a manner as will cripple the medical profession, medical men could not be expected to serve the State by leaving their practice to go to camp on terms which meant financial loss.

Society of Apothecaries of London.

THE following candidates having passed the required examinations, August, 1912, have received the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery and Midwifery:—R. V. Martin, P. M. Másiná, M. M. Patterson, J. E. Robertson-Ross and B. W. F. Wood.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Removal of Superfluous Hairs.—Boldt (*Journ. Amer. Med. Assoc.*, July 13th, 1912), points out the distress of mind which is caused to many women by the growth of superfluous hair on the face. He believes that in many instances this is caused by some abnormal condition of health, and it is found much more commonly in unmarried women than in those who are married; indeed, sometimes the hair disappears after a successful pregnancy. Various toxemias of intestinal origin also appear to be a prolific cause of this overgrowth of hair. In spite, however, of the most careful medicinal treatment, a certain number of patients remain for whom operative removal of the hairs appears to be the only satisfactory treatment. For this purpose, Boldt recommends electrolysis, and states that in his experience, one can by this method permanently remove the hairs without pain and without scarring. The method of procedure is as follows:—The area to be treated is thoroughly mopped with absolute alcohol, which, besides dehydrating the skin, tends to remove the sebaceous plugs from the follicles. The needle must be fine with an olive point, so that the shaft may be of a smaller diameter than the point. The needle is inserted into the follicle beside the hair, and a current from $\frac{1}{4}$ to 1 milliamperes passed, and the hair is epilated as soon as it loosens. When the hair is removed, the point of the needle is pressed directly on to the papilla, and in this way a much more limited cauterisation is efficient for its destruction than if an attempt was made to do this with the hair *in situ*. If the skin shows any urticarial irritability to the electrolysis, treatment should be postponed. Hairs closely grouped together should not be removed at one sitting, nor should the remaining hairs be treated till all reaction from the previous electrolysis has passed off. This is a matter of the very greatest importance in the prevention of scarring.

K.

Treatment of Ringworm.—Sequeira (*School Hygiene*, August, 1912), describes the method which he has adopted for the treatment of this disease by depilation with X-rays. The hair is cut close all over the head, and the distance from the margin of the hair in front to the nape of the neck is measured with a tape. At the mid-point of this line a cross is marked on the scalp with a blue pencil, and five inches in front of this another cross is marked, and also five inches behind the mid-point. On each side, just above the ear, another cross is made, which should be five inches from the centre point and five inches respectively from the anterior and posterior crosses. The X-ray tube is enclosed in a lead, glass, or metal shield with a wide circular opening. To the margin of this opening are attached three wooden pegs sloping towards each other. To make the exposure, the pegs are placed on the scalp so that the cross is exactly in the middle of the points where the pegs impinge. This ensures that the scalp is at the proper distance from the anode of the tube. The rays are passed till a Sabouraud's pastille, placed exactly midway between the anode and the scalp, changes to its proper orange tint. The process is repeated at each of the five points marked on the scalp, and so the entire scalp receives an equal radiation of the desired strength. With a good tube it is possible to complete the treatment of the entire scalp in 45 minutes, and in from 14 to 21 days the area so exposed becomes denuded of hair. During the period of the shedding of the hair, the scalp is washed each day and a dilute nitrate of mercury ointment rubbed in to prevent infection. From January, 1910, to May, 1912, 1,063 patients with tinea have been treated at the London Hospital by this method, and in no case was there permanent alopecia or any X-ray dermatitis produced. In view of the supposed danger to the

brain that may follow this treatment, Sequeira has made a careful investigation of the after-condition of many of the children, and "no single case is reported of any deleterious effect on the mentality of the children." Microscopic examination showed that 89.8 per cent. of the patients were infected with *microsporon tinea* and 10.2 per cent. with *endothrix*.

K.

Transplantation of Rib for Depressed Deformity of Nose.—Hays (*Med. Record*, June 22nd, 1912) reports that his patient, a young woman, had a typical saddle-back nose, and examination showed a total destruction of the nasal bones and the septal cartilage. The tip of the nose was held down by cicatrices. The deformity occurred during adolescence. Wassermann's reaction was negative. An incision three-quarters of an inch in length was made between the eye-brows, and was deepened down through the subcutaneous tissues, and a blunt dissection made to the tip of the nose with a periosteal elevator. The dissection was made outwards for some distance, to make plenty of room for the insertion of the rib. A piece of the ninth rib, about two and a half inches from its anterior end, was removed sub-periosteally, as it is unnecessary to transplant the periosteum. An incision was made through the periosteum of the frontal bone, and a dissection made between it and the bone for a distance of half an inch. The piece of rib was split down its entire length, the medullary tissue scraped away, the outer shell alone being used and inserted down to the tip of the nose, and the upper end slipped in between the periosteum of the frontal bone and the bone itself. The subcutaneous tissues were united to the periosteum overlying the rib and the skin united over this. The recovery was uneventful, and the cosmetic result excellent.

S.

Stricture of the Right Ureter Treated by Pyelo-Ureterostomy.—Kilvington (*Australian Med. Journal*, March 23rd, 1912) operated on a girl, *et. 20*, with apparently a dilated and painful gall-bladder. A large cyst was found lying posterior to the duodenum, and containing yellow fluid. It was evidently an extremely dilated renal pelvis, with an obstruction at the opening of the ureter, due probably to a gonorrhœal ulceration. The cyst was stitched to and drained through the anterior abdominal wall, where urine continued to come away, as the kidney itself was fairly healthy. Injections proved that no urine passed into the bladder from the right kidney. About three weeks later, the ureter was divided and implanted into a new portion of the renal pelvis by an anterior abdominal route, in the following way. The eye end of a probe was passed through the abdominal sinus into the renal pelvis, and made to impinge against its lowest part, which was opened. A silk thread was passed through the wall of the ureter, and then threaded through the eye of the probe. When the probe was withdrawn, the ureter was pulled into the renal pelvis, and secured by catgut sutures. The silk attached to the ureter was tied over a tube lying on the abdominal wall, thus taking some of the strain off the catgut sutures. For three months about equal quantities of urine passed through the sinus and into the bladder. A catheter was passed with some difficulty up the right ureter to dilate the obstruction. Soon after that the fistula closed. Three months later, the patient was free from pain, and passing 50 to 55 ounces of urine daily, and the fistula remained closed. The failure of urine to pass down the newly implanted ureter was probably due to the flap of ureter drawn inside of the pelvis acting as a valve. When this redundant flap shrank in size, its valve-like action would disappear.

S.

Migrations of a Foreign Body.—Salles (*Med. Review*, July, 1912) reports the case of a girl, *æt.* 2, who suffered for a week from a cough. There was a swelling like a boil on the left side of the chest, presenting a whitish point like a drop of pus. On attempting to wipe this away it was felt to be resistant. The writer grasped it with a forceps, and withdrew a 7 cm. straw with an ear 4 cm. long. Eight days before the child had visited a straw-worker, and swallowed the foreign body. After the removal of the straw, there was a slight gush of pus, and the air entered and was expelled from the cavity with each respiration. No complications followed. The straw appeared to have traversed the mouth, air passages, lung, and both layers of the pleura to the chest wall in a week, without causing much disturbance to health. S.

Cystomata and Torsion of Tube with Six Months' Pregnancy.—Marshall (*Journ. Obs. and Gyn. Br. Emp.*, xxi., 5) reports a case in which the symptoms pointed to hydronephrosis, and it was at first diagnosed as such owing to the tumour being situated in the upper quadrant of the abdomen, and the upper pole passing up under the right costal margin; the lower pole was defined about the level of the umbilicus, the tumour extending to the iliac crest. The daily secretion of urine varied from 23 to 42 ounces. The specimen consisted of an ovarian cystoma about the size of a term foetal head with a greatly enlarged tube with three twists upon it below the tumour. The operation was followed next day by miscarriage of a 6 to 6½ months' fœtus. F.

The Mullerian Origin of Some Broad Ligament Cysts.—Cole (*Journ. Obs. and Gyn. Br. Emp.*, xxi., 5) reports a case with illustrations in which this origin of a broad ligament cyst is demonstrated. The cyst, about the size of a hen's egg, is seen with the ovarian fimbria beneath it. An attachment to the Fallopian tube was demonstrated, and verified by serial sections to consist of tubal tissue which could be traced from the wall of the tube up to the margin of the cyst, although the lumen of the diverticulum nowhere actually communicated with that of either the cyst or the tube. A strand of tissue found stretched over the posterior wall of the cyst showed regular spaces, obviously representing the parovarian tubules cut across. F.

A Note on Early Rising after Cœliotomy.—Wallace (*Journ. Obs. and Gyn. Br. Emp.*, xxi., 5) records his experience during the past three years, and observations of 283 patients who were allowed up on or before the 10th day, the most popular day being the 7th. The patients are allowed to move about the ward, but are not discharged before the 15th day. He almost invariably employed Pannestiel's transverse incision using iodised catgut for closing, and does not think that the vertical incision would be sufficiently firm to allow an early rising, as in the cases when the transverse incision is used. In the majority of cases the results showed an improvement as regards muscular power and appetite. A few cases developed pyrexia when allowed up, one perineorrhaphy developed secondary bleeding, and three cases developed post-operative phlebitis. Post-operative constipation did not appear to be influenced. F.

Rupture of Pylsalpinx as a Cause of Acute Diffuse Purulent Peritonitis.—Brickner (*Surg. Gyn. and Obs.*, xiv., 5), records a case and from the literature to date has collected 90 others, this relatively small number of cases shows this complication of a fairly common condition to be rare. Of the 91 cases, 36 were not operated upon and all died. Of 55 operated upon 35 recovered and 18 died, two not known. The results of cases show the necessity of early operation, 19 treated within 12 hours of rupture all recovered, and of 28 operated upon within 24 hours only three died, one of these after three months. In most cases the rupture was spontaneous. The condition was most often mistaken for appendicitis, more rarely for ruptured ectopic gestation, in only a few cases was it diagnosed previous to operation. In several of the cases there was a

history of repeated attacks of severe pain over a period of a week, before the onset of the final attack most severe, followed by collapse and peritonitis. Unless the patient's condition is too bad to permit it the tube should be removed at the operation. F.

Umbilical Tumours containing Uterine Mucosa.—Cullen (*Surg. Gyn. and Obs.*, xxi., 5), has collected in all nine recorded cases. The most common glandular elements at the umbilicus are remnants of the omphalomesenteric duct. In the group under discussion the glandular elements have the histological appearance and arrangement exactly corresponding to those found in adenomyoma of the uterus, in one case the stroma was composed chiefly of non-striped muscle, in the majority the stroma was fibrous tissue with little or no muscle. These growths are benign. The nine cases are fully described and illustrated with microphotographs. F.

NOTICES TO CORRESPONDENTS, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

SHIP SURGERY.

A VALUED contributor, who has had unusual experience as ship surgeon on the principal routes to all parts of the world, has forwarded us an interesting paper on "Fractures at Sea" (which will be found in another column of our present issue) writes:—"I had quite a busy time coming out with 1,200 passengers and 1,400 total souls on board. We started off with measles and diphtheria. The former I was able to get at from the outset, but the latter cropped up all the way out, the last case developing two days from Sydney. I have had as many as 2,500 souls for a week, but 1,400 during six weeks in varying climates is somewhat different, and our average surgery attendance and visiting list worked out at about 75 per diem, quite a large club practice. We had a usual quota of accidents, and altogether I quite enjoyed it."

TIRO (Barnstaple).—A preparation of equal parts of paraffin oil and glycerine has been recommended to prevent the rain upon the glass wind screens from collecting in globules, and so obstructing the view of the driver. A few drops of the preparation is rubbed over the glass as soon as the rain begins, the effect of which is that no globules are formed.

DELETES.—It is not a general, but a useful, practice for the accoucheur to wear rubber gloves while attending a woman in labour.

Mr. B. GROOTS (Kensington).—We know nothing about the remedy our correspondent mentions. It is unlikely that anything really specific, in the accepted sense, has been found for the condition to which he refers.

SIGHT TESTS IN THE MERCANTILE MARINE.—A White Paper [Cd. 6,370], giving a report on the sight tests in the Mercantile Marine, was issued last week. It states that last year 7,309 candidates were examined. Of these 7,192 passed in form vision and 117 failed. Seven thousand candidates were successful in the colour vision tests and 192 failed. Of the latter 56 passed on re-examination.

AN INTENDING CANDIDATE.

THE next examination for the Royal Naval Medical Service will be held at the Examination Hall, Bloomsbury, on September 30th, and following days. Forms can be had of the Medical Director-General, at the Admiralty, Whitehall.

EX PARTE (Leeds).—Accepting the facts as stated, we think that our correspondent has acted wisely.

PRACTICAL PHARMACEUT (Hackney).—Optical rotation is, of course, an important property to determine in the preliminary examination of the essential oils, in addition to the refractive index. There appears to be some doubt in the minds of certain workers upon the subject as to the value of the refractive index, so much so that it is debatable whether its inclusion in the next British Pharmacopoeia is advisable.

DR. P. A. (Richmond).—The researches of Dr. J. D. Rolleston go to show that the blood-pressure is frequently subnormal in diphtheria, the lowest readings being generally found in the second week of the disease. In early paralysis the blood-pressure tends to fall.

Appointments.

- DAVIS, EDWARD D., F.R.C.S.Eng., Assistant Surgeon to the Nose, Throat, and Ear Department of Charing Cross Hospital.
- DENNEHY, JOHN J., M.B., B.S.N.U.I., Superintendent Tuberculosis Medical Officer for the County of Waterford.
- FRASER, A., M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Caistor District of Lincoln county.
- GILLESPIE, J. R., M.B., B.S.R.U.I., Medical Superintendent of the Tuberculosis Dispensary at Down County.
- GREEN, REGINALD, M.D.Durb., Medical Officer of Health to the Stroud Urban, Stroud Rural, and Nailsworth Urban Districts.
- MACDONALD, D. M., M.B., B.S.Aberd., Medical Officer to the Kennoway Parish Council.
- MAGENNIS, E., M.D.R.U.I., has been appointed Medical Officer to the James Street District of the Dublin General Post Office.
- MURPHY, ROBERT W., M.D., B.Ch., B.A.O., D.P.H.Dub., Assistant Medical Inspector of Schools to No. 1 District of the North Riding, Yorkshire.
- RADCLIFFE, A. H., M.B., B.S.Vict., Certifying Surgeon under the Factory and Workshop Acts for the Garforth District of the county of York.
- REDMOND, T. O'CONNELL, F.R.C.S.Irel., Medical Officer to the Clontarf District of the Dublin General Post Office.
- WARREN, F., F.R.C.S.Irel., L.R.C.P.Irel., Medical Officer to the Rathmines and Pembroke District of the Dublin General Post Office.
- WHEELER, W. IRELAND DE C., M.D., B.Ch. Dub., F.R.C.S.Irel., Medical Officer to the Central District of the Dublin General Post Office.

Vacancies.

- Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Corwen (Merioneth), Lisbellaw (Co. Fermanagh).
- Glasgow Maternity and Women's Hospital.—Two Indoor House Surgeons at the Hospital; Two Outdoor House Surgeons at the Hospital; and One Outdoor House Surgeon at the West End Branch (this appointment is open only to Lady Graduates). Further information of W. Guy, Secretary, 146 Buchanan Street, Glasgow.
- County Borough of Bootle.—Medical Inspector of Scholars and Assistant Medical Officer of Health. Salary £250 per annum. Applications to J. Henry Farmer, Town Clerk, Town Hall, Bootle.
- County of Denbigh.—County Medical Officer of Health. Salary £500 per annum, and actual travelling expenses, with £75 per annum for clerical assistance. A knowledge of Welsh is desirable. Particulars of W. R. Evans, County Offices, Ruthin.
- Manchester Children's Hospital, Pendlebury.—Resident Medical Officer. Salary first six months at £100 per annum, second six months at £120 per annum. Applications to Hy. J. Eason, Secretary, at the Hospital.
- Brecon and Radnor Asylum, Talgarth.—Assistant Medical Officer. Salary £170 per annum, with board, etc. Applications to the Medical Superintendent.
- Surrey Education Committee.—Medical Inspection of Children in Elementary Schools.—Assistant Medical Officer. Salary £250 per annum, rising to £300 per annum, with £50 per annum, out-of-pocket expenses. Applications to W. W. Finny, Secretary, County Education Office, Kingston-upon-Thames.
- Govan District Asylum, Crookston, near Paisley.—Second Assistant Medical Officer. Salary begins at £150 per annum, with board, etc. Applications to the Medical Superintendent, as soon as possible.
- Durham County Council.—Tuberculosis Medical Officer. Salary £500 per annum, with reasonable travelling expenses in addition. Applications marked "Tuberculosis Officer." Full particulars of Harold Jevons, Shire Hall, Durham.
- Children's Hospital, Temple Street, Dublin.—Assistant Physician. Applications to Hon. Secretary.

Births.

- BROWN.—On Aug. 19th, at Helston Lodge, Kasauli, India, the wife of Captain H. C. Brown, I.M.S., of a son.
- CHESTERS.—On Aug. 18th, at 111, Widmore Road, Bromley, Kent, the wife of Walter Horsfall Chesters, M.B., B.S.(Lond.), of a daughter.

- GREEN.—On Aug. 15th, at 37 Broad Street, Ludlow, Salop, to Dr. and Mrs. Edward Green, a son.
- HUTT.—On Aug. 16th, at 626, High Road, Tottenham, the wife of the late Charles Edward Hutt, M.R.C.S., L.R.C.P., of a daughter.
- MORLEY.—On Aug. 13th, at 6 Queen Street, Barton-on-Humber, the wife of E. B. Morley, M.B., B.S.(Lond.), M.R.C.S., L.R.C.P., of a son.

Marriages.

- HIGGS—SCOTT.—On Aug. 19th, at the Parish Church, Chandler's Ford, Frederick William Higgs, M.D., M.R.C.P., eldest son of Dr. and Mrs. Augustus W. Higgs, of Chelsea, to Dorothy Anderson, second daughter of Dr. and Mrs. J. Walter Scott, of Chandler's Ford (late of Truse Hill).
- SKAE—FRASER.—On Aug. 22nd, at St. Stephen's R.C. Church, Blairgowrie, Harold Traill Skae, M.D., Ch.B., youngest son the late F. W. A. Skae, M.D., F.R.C.S.E., Inspector of Asylums and Hospitals, New Zealand, to Marian Christal, only child of the late Dr. William Fraser and Mrs. Fraser, Ramsgate.
- TURNBULL—STRATTON.—On Aug. 1st, at Manningford Bruce, Wilts, Robert Cyril Turnbull, M.D., son of Henry Turnbull, of Scarborough, to Margaret, daughter of Frank Stratton, of Manningford Bohune.
- WADE—LONDON.—On Aug. 21st, at St. Thomas of Canterbury, Brentwood, Essex, Rubens Wade, B.A., M.R.C.S. L.R.C.P., of Bedale, Yorks, and The Grange, Windermere, son of the late Thomas Wade, The Grange, Windermere, to Phyllis Mary Landon, younger daughter of Colonel and Mrs. Frank Landon, Red House, Brentwood.

Deaths.

- CLAPTON.—On Aug. 20th, at Rose Villa, St. Stephen's Road, Canterbury, William Clapton, F.R.C.S., formerly of 30 Queen Street, E.C., aged 78.
- DENT.—On Aug. 26th, Clinton Thomas Dent, of 61 Brook Street, W., M.C. (Cambridge), F.R.C.S., Vice-President Royal College of Surgeons, Senior Surgeon St. George's Hospital, and Chief Surgeon Metropolitan Police.
- EDE.—On Aug. 25th, at Edencroft, Bramley, Surrey, Charles Ede, M.R.C.S.E., late Staff-Surgeon, R.N., aged 89 years.
- JONES.—On Aug. 24th, 1912, at The Elms, Burstard, near Billericay, Essex, Edgar Jones, M.R.C.S., J.P., aged 102 years.
- SCOFIELD.—On Aug. 17th, at "Elmfild," Half Moon Lane, Herno Hill, S.E., of angina pectoris, Harold C. L. Scofield, M.B., B.Sc., C.M., son of the late W. J. Scofield, M.R.C.S., of Birmingham, aged 48.
- SINCLAIR.—On Aug. 21st, at his residence, 325 Oxford Road, Manchester, Sir William J. Sinclair, M.D., J.P.

OPERATIONS—METROPOLITAN HOSPITALS.

- WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynaecological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopaedic (2.30 p.m.), Soho Square (2 p.m.).
- SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).
- MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.), Samaritan (Gynaecological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopaedic (2 p.m.), City Orthopaedic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, SEPTEMBER 4, 1912.

No. 10.

NOTES AND COMMENTS.

Street Dangers and Motor Traffic. THE recent rapid growth of motor traffic has correspondingly increased the danger to wayfarers in our public highways. In the great centres of population the toll thereby laid upon our citizens in loss of life or limb has mounted gradually to breaking strain. A certain amount of risk, humanly speaking, is inseparable from all kinds of vehicular traffic, but it has been brought home to the mind of the man in the street that the havoc wrought by mechanically driven vehicles has passed the breaking strain of endurance. Beyond a doubt the greatest danger and nuisance arises from the heavy motor omnibuses that thunder through our streets, regardless of the rights of pedestrians, reckless of speed limits, destroying the peace, the health, the very structure of the houses of those hapless persons who live alongside their selfish destructive routes. The question now forced upon town dwellers is whether this dangerous nuisance is preventable, and if so, by whose authority and in what manner should it be prevented? It is intolerable that a small knot of shareholders should be permitted to disturb the amenities of urban life in their selfish lust for dividends, which after all are drawn from the pockets of the injured parties. Moreover, the omnibus companies live only by the sufferance of the ratepayers, who by the irony of circumstances are called upon to pay for the maintenance of the roads worn out by the companies that have thus established a monopoly at their cost.

What is the Remedy?

THERE are two organisations to which the citizens may look hopefully for relief from the street motor peril, namely, the local councils and the police. In London, and in certain other large towns, the problem is complicated by the fact that municipal trams are run in opposition to public vehicles owned by various companies. There is abundant opportunity of control, however, open to the London County Council and to provincial authorities in the way of fixing routes, controlling speed, weight of vehicles, conditions of concession, and so on. Of all these things the great central evil is that of speed—upon that depends to a great extent the noise, risk to pedestrians, dangers of collision, nuisance to householders along route, in a word, it is the rock-bed fact, the core, the Alpha and Omega of this intolerable motor danger. All this may be commended to the police, who in London have issued a warning notice showing that they are making a serious effort to grapple with the evil. Drivers of motor vehicles are notified that in case of accident the question will in future be raised of the renewal of license. For a day or two after the issue of the

notice there was a marked diminution of speed on the part of the motor omnibuses, which crawled along silently in streets through which they had previously raced and thundered. But their caution speedily evaporated, and they are now dashing along with the old fierce joy engendered of rapid locomotion.

Selfish Motor Omnibuses.

CAN the police control the speed limit?—if so, they will confer an unspeakable boon upon the public. The writer knows a hill in a western suburb down which the motor omnibuses thunder at a speed far beyond any safe or reasonable limit. Neighbouring houses rock and tremble as with an earthquake at the passage of each car. Ceilings crack and fall, sleep is banished, a species of pandemonium reigns outside from early morning to midnight—all for the sake of trading companies anxious to swell their dividends by working their vehicles at excessive speed. If the omnibuses were driven at moderate speed the risk and the nuisance caused by them would be reduced to vanishing point. The above mentioned street is a convenient spot for drivers to make up time, and therein lies the explanation of their apparent recklessness. Unless they complete their journey within given limits they incur the risks of fine and dismissal. It is the rules of the company in fixing their time tables with too short an allowance for route-journeys that lies at the root of this public nuisance and danger. In order to keep up to time the drivers have to force their pace—or, worst of all, to race with other vehicles. Dangerous as the practice of racing was in the case of horse-omnibuses, it waxes a hundredfold with the motor omnibus. It is some comfort to learn that the London police have taken the matter in hand, for their methods are usually thorough when once they have been roused into action. The two points we specially commend to their notice are the speed limit and the companies' time-tables. Why cannot some regulation be brought in compelling every motor vehicle to carry a whistle that sounds automatically and continuously when a certain speed has been attained? Such an appliance has been invented, and its general use would immensely lighten the problem of the control of street traffic.

The Norwich Flood.

THE month of August, 1912, will live long in history as the wettest on record in the United Kingdom. It has spelt ruin to the farmers and marred the holidays of a large section of the population, while it has wrought havoc in various other directions. The experience of the ancient City of Norwich has been appalling. The floods at one time practically cut off the citizens from the outer world. The electric light

failed, whole streets were under water, houses demolished, householders rescued in boats, children and some adults drowned, and, generally speaking, the whole place given over to ruin and desolation. Fortunately the state of the weather improved somewhat the end of the week, and the waters began rapidly to abate. The natural result of this terrible experience is an inevitable aftermath of sickness, a great deal of which is due to shock, deprivation of food and exposure to wet and cold. A certain amount of enteric fever has been reported, and, in any case, might be expected in so ancient a city where the whole drainage system has been submerged and the water supply disorganised. This calamity which has overtaken Norwich suggests the desirability of investigating the engineering possibilities of the district, with a view of providing some alternative routes of water exit in flood time. The flatness of the county renders any effectual scheme one of difficulty, but something might perhaps be accomplished by the resources of modern civil engineers. At any rate, it might be feasible to construct some sort of defence in the city itself for low-lying houses. The cutting of an extra storm conduit, together with the widening, deepening, and straightening of the present waterways, will doubtless receive careful local and Governmental attention as the result of the unparalleled catastrophe which has overtaken one of the most interesting of our ancient and historic towns.

Colour Blindness at Sea.

In connection with our recent remarks on the unsatisfactory nature of the Report of the Departmental Committee on Colour and Sight Tests, we note that the document in question comes in for vigorous criticism in the September number of *The Ophthalmoscope*, amounting, indeed, almost to an indictment of the Committee's findings. Our contemporary considers the Report to be "singularly defective" on the following specific grounds:—First, because it fails to recognise that accidents caused by defective vision have happened, and do happen, at sea; secondly, because it disregards the fact that a sensible proportion of officers at sea are colour-blind and have defective form sense; thirdly, because it retains the Holmgren wool test, which has been shown to be inefficient, and which allows a large percentage of colour-blind persons to pass; fourthly, because it suggests the use of a lantern, devised by the Committee, which is unprovided with neutral modifying glasses; and, finally, because it persists in recommending the retention of examiners who are admitted to be too inexpert to employ anything like a proper appliance for the examination of colour vision. This is eminently a matter for the consideration of Parliament, and would be best raised by some one of the medical men who are members of the House.

LEADING ARTICLES.

THE NATIONAL INSURANCE ACT.

THE dispute between the administrative Government and the medical profession has naturally abated somewhat in energy during the holiday season. Now that the Act is in force, however, a speedy solution of the problem must be forthcoming. A few recent events of significance in the struggle may be noted. First, the resolution arrived at by the Liverpool meeting that medical men should be free to accept posts and give service under that part of the Act relating to sanatorium benefits. The

next was the resolution requesting medical men to resign their posts on the Advisory Committee: advice that has been rejected by a number of the members concerned, amongst whom are men whose names carry great weight and influence in the profession. Next comes the resignation of Dr. Herbert Jones, a member of the Joint Advisory Committee, who had previously declined to accede to the request of the British Medical Association to withdraw from the committee. The reason given for his reconsideration is as follows:—"Being a medical officer of health, I thought I ought to yield to the representations of the local doctors who advised me to resign." That explanation will appear sufficiently explicit and cogent to all who value loyalty and firm collective unity above the mere dictates of individual opinion. Right or wrong, no great purpose is possible of fulfilment by any section or class of the community unless it be by the subjection of the views of the minority to those of the majority. On this ground alone the refusal of those men, however pure or disinterested their motives, cannot be approved, inasmuch as it divides our councils on the eve of battle. To split our ranks is to play into the hands of the astute politicians, against whom the sole hope of ultimate success lies in the solidarity of our union. Dr. Jones may be congratulated, therefore, on his surrender of private views in favour of a policy deliberately adopted by the majority of the medical profession. There is much to be said for those who cannot uphold the tactics which sought to withdraw the medical element from the Advisory Board at the very moment when their advice would have been of supreme value. Nevertheless, we hold that it is the duty of every medical man to support the policy agreed upon by the representative body of the British Medical Association, which, in spite of various shortcomings, must necessarily form the central fighting organisation of our profession. On such grounds it may be hoped that the example of Dr. H. Jones will be followed by further resignations of members still retaining a seat on the Advisory Committee. The last point to which attention may be called is the declaration of Mr. Masterman last month to the effect that if to raise another £4,000,000 for medical fees were the only alternative to the suspension of medical benefit, then without any doubt medical benefit would be suspended. The *Daily News*, whose hostility to the medical profession throughout the present controversy has been conspicuous, accepts that declaration as meaning that the approved societies would take the money and make their own terms. The prospect of such an event fills its editorial heart with joy, and it is pointed out that past experience has shown medical men cannot fight the societies in the open, while there is a constant supply of young doctors from England, Scotland, Ireland and Wales who want a regular income such as would be forthcoming from the clubs. The *Daily News* winds up with the familiar taunt that medical men should be wary of being exploited for political purposes, neglectful of the

fact that the attempt to play fast and loose with the interests of the medical profession by the Government has led to the whole of the present struggle. In a situation beset with difficulties, success, it may be repeated, lies only through the gates of unity. Taking a hint from the enemy, we venture to appeal most solemnly to the younger generation of medical men to stand loyally by the profession they have adopted, and not to sacrifice future collective interest for the sake of an immediate selfish advantage. Some such advice might well be circulated amongst junior members of the profession by the British Medical Association. Lastly, in view of the present critical state of affairs, it is incumbent upon every medical practitioner to decide forthwith whether or not it would be wise to join the public medical service which has now reached an advanced stage of organisation.

A RESIGNATION FROM THE BRITISH MEDICAL ASSOCIATION.

THE public newspapers of Monday, September 2nd, comment on the resignation of Dr. Duncan Forbes, Medical Officer of Health for Brighton, from the membership of the British Medical Association. At the present juncture his action is of extreme importance to the medical profession, and his public explanation, as given in the lay press, demands our serious attention. It is reported in a London journal that Dr Forbes declined to carry out the association pledge, when called upon by the local branch, by refusing to discharge official duties in connection with the Insurance Act. To use his own words:—"Up to a few days ago," he writes, "I thought that was all that was expected from public officials. I thought that it was recognised that the first duty of a public official was to advise and assist public bodies in the manner he judged most likely to promote the efficiency of their administration. I now gather from the Brighton Division that the public official who remains a member of the B.M.A. must follow any policy laid down by that body, and must not assist his council in carrying out any alternative policy in conflict therewith." Dr. Forbes then alludes to the advertisement for whole time medical men for medical inspection and treatment, published by the Education Committee at his suggestion, in opposition to the views of the local profession. Reverting to the Insurance Act Dr. Forbes asserts, "the Brighton Division wished me to refuse to do work which is included in the comprehensive list of my duties, in order that the Council might be embarrassed in carrying out their legal obligations. It now transpires that the Brighton Town Council has appointed Dr. Forbes chief tuberculosis officer for the borough for the purposes of the Insurance Act. At present it is somewhat difficult to grasp the situation thus created. The resolution of the representatives, meeting at Liverpool expressly sanctioned the holding of sanatorium posts by members. That surely covers Dr. Forbes so far as the sanatorium benefits of the Act are concerned, but possibly the

disapproval of those of this division of his action in the matter of the school medical officers was the chief determining factor. In any case the breaking of a deliberate pledge is and always must be a serious matter. No man can serve two masters satisfactorily, and it is only natural that when a choice between them becomes obligatory a direct employer should come before a voluntarily adopted organisation. The situation is not palliated by the fact that a paid official post enters into the proceedings. Obviously it is a most undesirable state of affairs that a medical officer of health should not be on harmonious terms with the medical men in his district, nor can it apparently be to the interests of a large and populous town like Brighton that its chief health official should be burdened with additional special duties. The burden of work for a conscientious medical officer of health is heavy and increasing, and is usually more than enough for the energies of one man. The Local Government Board, however, appear to have sanctioned the appointment in question. From various points of view we are reluctantly forced to regard the resignation of Dr. Forbes as ominous of further dissensions in the medical profession with regard to the administration of the Insurance Act.

CURRENT TOPICS.

Tuberculous Cows.

THE *Westminster Gazette* has been publishing a series of able articles on the milk question. In one of the latest of these the problem of destruction of tuberculous cows is discussed, and the great difficulties in the way, especially on the score of expense, are set forth. In the first place, it would be necessary to set up an efficient system of inspection. It is clearly shown that this could not be carried out without a staff of at least 70 to 80 inspectors, whose time would be fully taken up with their duties. Assuming that no superior staff was called for, and that the inspectors could be got for a salary of £500, the outlay in this direction alone would approach £400,000 a year. The estimates of all authorities who have investigated the subject give an average approximately of 40 per cent. of tuberculous dairy animals among the herds in this country—a total of some 1,120,000 animals. To slaughter the whole of these animals and to compensate the farmer at the lowest possible rate would mean the expenditure of a vast sum. The "wasters" and the cows with tuberculous udders call most urgently for extermination. The number of these is reckoned at about 4 per cent. of the animals in the country, and the cost of their destruction is estimated at more than £500,000. It is urged that the farmer should be encouraged in every way to get rid of these infectious animals, and that with systematic slaughtering there should be increased stringency in the matter of housing. In Holland a farmer who receives compensation obtains the money on condition of giving guarantees as to keeping his cattle in sanitary conditions in future, and as to avoiding the introduction of

animals likely to be infected. These *Westminster Gazette* articles deserve publication in permanent form. They are of much more than passing interest.

Women's Sick and Wounded Convoy Corps.

THE existence of this corps forms one of the numerous similar signs of the times, all pointing in the same direction. Women are now taking part in all kinds of movements in which the first essential qualification is a standard of physical fitness that would not have been thought attainable by the sex a few generations ago; and these activities nowadays are taken as a matter of course, not in any way calling for public criticism. During the past week the corps has been undergoing its third year's training in camp at Rottingdean. The object is so to train the members, that they may be competent to do all that may be required for the sick and wounded in war during the days of transit from the field hospital to the base. The training comprises a three years' course in the following subjects:—First aid, physiology, hygiene, sanitation, field nursing, and practical work in hospitals; cooking; laundry and housewifery; signalling; ambulance work; improvisation of bandages, splints, stretchers, etc.; adaptation of buildings for hospital purposes, and of carts and railway trucks into vehicles suitable for transportation of the wounded; and riding and the care and management of horses. The corps leads a military disciplined life in camp, the drills, exercises, and instruction, including swimming and life-saving and treatment of the apparently drowned, filling the day. The night guards are mounted by the women, and at least once during the training the whole corps is turned out by a night fire alarm.

Rural Housing and Building By-Laws.

THE health and the ethical improvement of the people depend largely upon the housing problem, and this again depends upon the possibility of providing dwellings which can be let at rentals affording reasonable interest for the capital invested. The difficulties in doing this have up to now been increased by the stringency of by-laws which enforce the use of both expensive materials and methods of building. The Local Government Board has therefore now wisely issued a circular which, by allowing greater freedom to authorities, will, if acted upon, facilitate the erection of small dwelling-houses throughout the country. The circular points out that by-laws are intended to act in the interests of the inhabitants and to prescribe standards of building securing stability, protection from fire, and healthy conditions, and it is undesirable that by-laws should afford ground for the suggestion that they are unnecessarily restrictive. New methods of construction demand periodical revision of by-laws. For example, the earlier forms of by-laws, framed with particular reference to brick construction, imposed conditions as to wall thickness, and the use of materials which are inappropriate to types of construction now in use, such as building with hollow block, or slabs of terra cotta, concrete, and the like material, reinforced brickwork, or reinforced concrete. Many of

the older by-laws do not provide for hollow and half-timbered walls and steel or other framed walls hung with tiles, slates, etc., filled in where necessary with incombustible materials. Isolated cottages in every way satisfactory can often be cheaply built mainly of timber; and the method of constructing cheap houses of concrete—"poured" or "moulded" houses—as suggested by Edison, and extensively used in the United States, might well be introduced into this country.

House Drains and Sewer Air.

WITHIN the last few days has been published the report on house drains by the Departmental Committee, the appointment of which by Mr. John Burns was notified in these columns some time ago. The most interesting item for the medical reader in the report is perhaps the statement of the difference of opinion that prevails as to the effects of sewer air upon health. The report points out that formerly outbreaks of many diseases were unhesitatingly ascribed to defective drains and sewers, and that now although sewer air is not generally regarded in such a dangerous light, a considerable body of medical opinion retains the view that certain diseases, notably typhoid fever, diphtheria, quinsy and sore throat, and certain "septic" diseases, are fostered or produced by sewer air or drain air. On the other hand, many authorities believe that if past outbreaks of disease attributed directly to sewer air could be reinvestigated in the light of present knowledge some other explanation of the facts ascertained would be patent, and that emanations from drains and sewers, although harmful in the same way that any offensive air may be, are not the cause of and do not foster the spread of any disease. The problems involved seem to be in a great part clearly bacteriological; they do not on the face of them appear extremely difficult, and in view of the number of able workers in this field, their solution should not now be long delayed.

A Medical School for Diseases of the Chest.

THE rapid growth of specialism in medicine appears to be gradually modifying the conditions of medical teaching in this country. Little by little new centres for clinical instruction are springing up where those who wish to obtain extra qualifications in certain subjects can obtain the necessary experience. One of the latest additions to these post-graduate institutions is that recently established in connection with the Royal Hospital for Diseases of the Chest, City Road, which, we understand, will be open about the middle of next month. The working of the sanatorium benefit under the National Insurance Act, as well as the increased activity in regard to the treatment of tuberculosis in general, has created a demand for the "tuberculosis physician," who, whether he be a general practitioner or a consultant, is now expected by the public to possess more than the average amount of knowledge of this particular disease. According to the statement published by Dr. Barty King, the acting dean of the new Medical School for Diseases of the Chest, it is intended that instruction shall be given in the diagnosis and treatment of pulmonary tuberculosis, and it is hoped that the school will become a training centre for those who wish to qualify themselves for

dispensary and sanatorium appointments. Clinical teaching and practice will be carried out in the wards, out-patient department, and tuberculosis dispensary. Instruction will also be given in bacteriological, X-ray, tuberculin, and sanatorium (adults and children) methods. Special opportunities will be granted for research work to those who possess the requisite qualifications. This is a movement of such importance that the co-operation of other chest and consumption hospitals might well be secured in order to provide one central training school. Only in this way can the dissipation of energy be prevented.

The Marching Powers of Troops.

ACCORDING to military authorities the increased mobility of armies, which is a noticeable feature of present-day tactics, has led to no diminution in the amount of marching required of soldiers, but rather an increase. From the physical standpoint the different factors influencing the marching powers of troops have always been a subject of great interest to army medical officers. In the course of a thoughtful and practical paper read before the Section of Navy, Army, and Ambulance at the Liverpool meeting of the British Medical Association, Captain N. Dunbar Walker, R.A.M.C., stated that the load carried by the soldier on the march should be little more than 47 lbs., or one-third of the 10 st. man's body-weight, the official 59 lbs. odd, including clothing, being somewhat too much for many of the men. More instruction appears to be needed in marching while carrying full loads, including ammunition. The maintenance of a regular pace and the cultivation of the regimental *esprit de corps* are considered to be important accessory factors. It may be noted also that the stimulating properties of music, which have been physiologically attested, are mentioned as being most helpful in keeping up the spirits of the men. The tendency to move troops at night is to be deprecated, since the loss of sleep is bound to tell unfavourably upon the physique. To compensate for the loss of water from evaporation during an ordinary march of fourteen miles in a temperate climate the one and three-quarter pints contained in the regulation water-bottle should be sufficient.

The Health of School Teachers.

So much is now being done to improve the health of school-children that the physical condition of the teachers themselves is deemed quite a secondary consideration. Indeed, it is safe to say that in many quarters the health of those who are entrusted with the education of children is never given a thought. It is true that a medical examination is insisted upon by a few authorities, but beyond this little, if any, attention is paid to the health of teachers. The work of teaching makes a considerable demand upon the nervous force of both men and women, many of whom show distinct evidences of neurasthenia at the end of a hard term. Apart from maladies of the nervous system, functional or organic, to which teachers as a profession are liable, there are the effects of taking too little physical exercise and recreation to be considered. The teacher's work, even in day-schools, does not end when the pupils are dismissed, for there are other duties to perform out of school hours. It is difficult for a teacher to obtain that amount of physical and mental relaxation necessary to keep him or her in a fit condition, hence the inevitable staleness of mind and flabbiness of muscle that is apt to result from a too close application of evening study. A course of lectures on

"Hygiene of the Teacher" might well be included in the teacher's curriculum, for the health of those who teach must not be overlooked in the efforts to improve the physical condition of the taught.

Beri-Beri and the Yage Plant.

THE deprivation of the phosphatic contents of white rice in the process of milling or polishing has been held by many competent observers to be one of the causes of beri-beri. According to Dr. Funk, of the Lister Institute of Preventive Medicine, the active principle known as "vitamine," if given to a pigeon the victim of the disease, will restore the bird to a normal condition of health. It now appears that the yagé plant, found in that portion of the Republic of Colombia known as the Caquetá district, is accredited with curative properties, and, from a letter from Dr. R. Z. Bayon, recently published in the South American Supplement of the *Times*, its action in beri-beri is said to have been most beneficial. Dr. Bayon, who has travelled for some months in the heart of the Caquetá district, states that decoctions of the plant not only cured two rubber hunters but also produced some peculiar telepathic effects upon those to whom it was administered. It is a matter for regret that botanical details respecting the plant are lacking, but it is understood that specimens will be investigated in this country with regard to its supposed curative properties in beri-beri. Whether the active principle of yagé will prove to be identical with "vitamine" may, perhaps, be revealed by chemical analysis.

PERSONAL.

DR. CHARLES W. HAYWARD, barrister-at-law, of Liverpool, has been adopted as the prospective Liberal candidate for Radnorshire.

SURGEON-GENERAL L. E. ANDERSON, A.M.S., P.M.O., of the Bareilly Brigade, has been appointed Deputy-Director of Medical Services, 8th (Lucknow) Division.

PROFESSOR J. LORRAIN SMITH, M.A., M.D., F.R.S., of Manchester, has been appointed Professor of Pathology to the University of Edinburgh in succession to Professor Greenfield.

AFTER twenty-four years' service, Dr. Joseph Wiglesworth has intimated his intention of retiring from his position of Medical Superintendent of the County Asylum at Rainhill.

MR. F. COOK, B.Sc., M.B., B.S., has been awarded a Research Scholarship in Agricultural Science, in the department of animal nutrition, by the Board of Agriculture and Fisheries.

THE LORD MAYOR OF LONDON, Sir Thos. B. Crosby, M.D., F.R.C.S., will preside at the annual dinner of the old students of St. Thomas's Hospital to be held on Tuesday, October 1st, at 7.30 p.m.

AMONG the exhibits at the Royal Photographic Society's annual exhibition, at the Suffolk Street Galleries, are to be seen some interesting plastic X-ray photographs by Dr. Thurstan Holland, and some radiographs by Dr. J. Hall-Edwards.

As we go to press we have received, with profound regret, the news of the death of Mr. L. A. Bidwell, F.R.C.S., Surgeon to the West London Hospital, following upon an operation for appendicitis. A full obituary notice will appear in our next issue.

A CLINICAL LECTURE

ON

PERFORATION OF THE STOMACH AND DUODENUM, WITH SPECIAL REFERENCE TO THE EARLY SYMPTOMS. (a)

By G. GREY TURNER, F.R.C.S.,

Newcastle-upon-Tyne.

LADIES AND GENTLEMEN.—I was very pleased to fall in with the suggestion of the Superintendent, and lecture on some point of surgical interest, because it is very important that those of us who have the opportunities of working in large hospitals should do what we can to bring the results before the general practitioners, who do not, perhaps enjoy the advantages that we do. This subject is a very practical and important one. Perforation of the stomach or duodenum is not only a terrible accident as a complication of gastric or duodenal ulcer, but cases of the kind furnish some of the most awful calamities which affect the community. As a mode of death it has been recognised for ages, but a complete understanding of its frequency and of its natural history has only come as a result of the invasion of the abdomen by the surgeon. Prior to 1892 when, on the suggestion made by Mickulicz, life was first saved by operation in a case of perforated gastric ulcer, this accident was almost universally fatal, and many notable personages lost their lives in this way. Nothing can better show the change which has come over the surgery of the acute abdomen than the number of lives which are now annually saved by timely interference. In 1900, I operated on eight consecutive cases without losing a patient. But in order to realise our responsibility in this matter, we must recognise that there are many cases which run a very rapid course towards a fatal termination, and that our measures must be prompt if they are to be successful. In 1904 I saw a young man, *æt.* 25, who had suffered from indigestion for two years. One evening he had sudden pain and collapse. A surgeon was telephoned for, but, not appreciating the full importance of the condition, he advised waiting until the morning. In the morning I saw the patient, and found him moribund, with lips blue, hands cold, an almost imperceptible pulse, and the abdomen tender and rigid all over. He died 27 hours after the perforation had occurred. Even the full significance of these symptoms is not always appreciated at the present day. On the 8th of this month a patient was admitted into the Newcastle Infirmary, a strong man, 40 years of age. He had had indigestion only three weeks. Twenty-four hours before his admission he was seized with severe pain. He was so ill and the pain was so intense that he was supposed to be the subject of acute poisoning, and was treated accordingly. On arrival at the hospital he was moribund, and died twenty-nine hours after perforation. An acute duodenal ulcer was found just beyond the pylorus. The frequency of perforation is difficult to estimate, and I think it is doubtful whether it is as much more common as is alleged, though certainly it is now much more frequently recognised. In 1889, no patient with this condition was admitted into Newcastle Infirmary, but ten years later there were 18 cases, with three deaths.

Is there an acute perforating ulcer? The average age of a series of patients operated upon for ruptured gastric ulcer and duodenal ulcer was

found to be 28 years, while the average age of cases operated upon for chronic symptoms by gastro-enterostomy was 40 years. This may mean that cases which safely run the gauntlet without perforation are merely spared for surgical treatment later on. So we should expect to find a history of such length as to correspond to the difference in the average age, but that is not so. In 57 cases of operation on non-perforating duodenal ulcer, the ulcer was found to be on the inner wall in all. In some there was a second ulcer or scar on the outer wall. In operating on 51 cases of perforating gastric or duodenal ulcer, the conditions suggested chronicity in 27, whereas in 24 the ulcer was acute. These facts suggest that there is a special type of ulcer whose principal characteristic is a proclivity to perforate. This is important, as it has a great bearing on the diagnosis and on questions of treatment, and especially on whether or not gastro-enterostomy should be performed at the time of the operation. So we must recognise *perforation as an accident almost peculiar to one type of ulcer, and as an accidental complication of another type.* The incidence of the two varieties appears to differ in the stomach as compared with the duodenum, for in the stomach the proportion of perforations of chronic types of ulcer is greater than in the case of the duodenum. But the discrepancy is easily explained, because in the duodenum the chronic non-perforating ulcer is on the inner wall, and is protected by the intimate relations of the pancreas. And the same thing is illustrated in the stomach, for of gastric ulcers in general 32 per cent. are on the posterior wall, but of those that perforate only 17 per cent. are in that situation, because such ulcers early have adhesions to the pancreas.

Let us consider the features of the ulcers which perforate. The typical perforating acute ulcer is nearly always near the pylorus, on the anterior wall or in the first part of the duodenum. Various reasons have been given for this, but none appear to me to be very illuminating. Still, there must be some simple explanation. These ulcers of acute kind are rarely larger than a threepenny bit, and have a punched-out appearance, with edges which are clean-cut and not heaped up. They may be multiple, but multiple perforations are uncommon. When perforation occurs, it appears as if the whole bottom of the ulcer had sloughed away, leaving a hole almost as big as the original ulcer; sometimes it is merely a small slit perforation. What is known as the kissing ulcer is frequently found. You often find immediately opposite the chief ulcer another, and ulcers on the inner wall of the duodenum often bear this relation to those on the outer wall. From examination of many specimens I have concluded that the second or kissing ulcer is often of the acute variety. In the duodenum, chronic ulcer is probably always on the inner wall, and the kissing ulcer is just opposite, and is acute. This we have learned from experience, not only in the necropsy room, but also on the operating table, because there has been

(a) Delivered at the Polyclinio, Chenies Street, London, W.C., Tuesday, July 16th, 1912.

considerable attention given to pyloroplasty, and the parts have been carefully examined, and we find, commonly, ulcer on the outer wall of the duodenum is associated with ulcer on the inner wall. That is important because if, at the operation, the surgeon finds an acute ulcer on the outer wall of the duodenum which has perforated, he is tempted to say it is only necessary to suture it. But if there has been a long history there will probably be a second ulcer on the inner wall, and therefore, something further must be done than merely closure of the perforating ulcer. Chronic ulcers are about the lesser curvature, of the saddle variety, and, perhaps, are leading to commencing hour-glass stenosis of the stomach. In chronic ulcer there is always surrounding inflammation, and œdema, with thickening of the peritoneum and vessels leading to the site of the ulcers, and the area is friable, so that the sutures will scarcely hold. I have brought a specimen which shows chronic ulcer on one side, and an acute ulcer on the other side, and a small glass rod has been passed through the perforation. Of my 51 cases, there were only 2 on the posterior surface of the stomach.

I will now refer to one or two anatomical points. The peritoneal cavity is only a potential cavity, and is normally occupied by the contained viscera, without dead spaces. But the peritoneal cavity is not an uncharted sea, and I direct your attention to this diagram. Fluid, following perforation, first runs into what we know as Morison's pouch, then down the outer side of the colon and outer side of the cœcum, and so into the pouch of Douglas. The importance of that is, that commonly patients complain, when they have this trouble, of pain about the cœcum, and sometimes there are the symptoms usually associated with appendicitis, and perhaps there may be trouble with micturition. In its passage the fluid may flow over the liver, and it is there you find sub-diaphragmatic abscess in cases which have perforated some time before. With regard to the physiology of the peritoneum, it is exceedingly sensitive, and that explains why a small leak is attended with some pain and evidences of shock. But there is another point of importance, and that refers to the question of the preparedness of the peritoneum. In the early days of ovariectomy, you may recollect that the cases which did badly and died were those in which the surgeon was perfectly simple, in which the surgeon simply tapped and removed the cyst, yet the patient died in 48 hours of acute peritonitis. But in the cases in which there were adhesions, and in which the cyst had to be torn out, the patients recovered. It means that in the one case the peritoneum was taken unawares, and in the other, where there were adhesions, it was prepared by previous infection. And the upper part of the peritoneum is much more sensitive than is the lower part, so that the symptoms when there is a collection of fluid in the pelvis are not so acute as when the collection is higher up. Both before and after operation this is of importance, because the patient should be encouraged to adopt the sitting posture, so that the fluid may be induced to go into the pelvis, where it will be less harmful. It is also important at the operation, because it shows that, no matter how much fluid there is in the upper part of the abdomen you must look in the pelvis for fluid also. I think it is proved beyond doubt that spontaneous recovery from ruptured gastric or duodenal ulcer can occur. At one time that was not thought possible. One easily understands how that can occur in the case of purely localised collections, but I have proof that it can take place in cases in which it was generalised. It is well to recognise that there are certain definite classes of perforations, or

results of them. There is the *acute perforation with general extravasation*, when an ulcer suddenly ruptures into the healthy unprotected peritoneum, and the statistics I present to you in the tables all refer to that class of case. There is *sub-acute perforation with a limited degree of extravasation*, and there is *chronic perforation without extravasation*, the ulcer slowly eating its way into neighbouring organs.

With regard to the clinical aspects of the subject, at what age does perforation occur? Cases have been met with, in children's hospitals, in little babies, but they are very rare; but several have been operated upon at 12 and 13 years of age. My youngest case was that of a boy of 18, and my oldest was a man, æt. 70. My colleague, Mr. J. W. Heslop, operated upon a woman, æt. 72, for ruptured gastric ulcer. The average of my series works out at 30 years for gastric ulcers, and 33½ years for duodenals. Then there is the question of sex. It is curious that in my series, and in most other similar series, most of the gastric cases were in females, while among the 34 cases of duodenal ulcer there was only one female.

An interesting question is: Can we tell when perforation is about to occur? I believe that is not possible. Some cases develop indigestion just before, or have an increase of previous troubles, but indigestion may certainly disappear. If the patient has an increase in digestive troubles which suddenly disappear, that is of the gravest significance, because it means gangrene of the base of the ulcer. Other patients may be unaware that they have so dangerous a disease; indeed, they may have been exceptionally well just before the onset of the perforation. I have known the accident take place while the patient was actually lying in a ward undergoing medical treatment. I have seen a big, strong labourer who was so suddenly struck down at his work that it was regarded as a case of sunstroke. On a Saturday a man consulted me on account of stomach trouble which he had had for ten years, and which had lately become worse. I strongly advised that he should have the operation of gastro-enterostomy done, and made arrangements for the patient to enter a private hospital on the Monday. But on that day he perforated, and had to be at once taken to the nearest infirmary. One patient recently operated upon had called upon a doctor for a bottle of medicine for stomach trouble, and on her way home she had perforation. As soon as the diagnosis of ulcer has been made the patient should be placed under the treatment decided upon, and warned of the possibility of the occurrence of perforation. It may occur at night, but it usually happens in the daytime. That is of some importance in considering the differential diagnosis, because it is common for appendicitis to start in the early hours of the morning, awakening the patient from sleep. I want to put before you some statistics, showing how very important is early recognition and treatment.

PERFORATED GASTRIC AND DUODENAL ULCER.— PERSONAL CASES.

Gastric Cases.

17 cases with 3 deaths = 17.6 per cent.

Average number of hours between perforation and operation = 10½.

Longest interval between perforation and operation = 28 hours with recovery.

Shortest interval between perforation and operation = 5 hours with recovery.

In the cases that died, 9½, 10½, and 20 hours elapsed before operation.

In 5 cases gastrostomy was performed—2 died.

In 1 case gastrostomy with gastro-enterostomy—recovered.

In 2 cases gastro-enterostomy—recovered.

In 2 cases pyloroplasty—recovered.

Duodenal Cases.

34 cases with 5 deaths = 14.7 per cent.

Average number of hours between perforation and operation = 12½.

Longest interval between perforation and operation = 36 hours with recovery.

Shortest interval between perforation and operation = 3 hours with recovery.

In the cases that died, 9½, 16, 24, 28, and 28 hours elapsed before operation.

In 1 case gastrostomy with gastro-enterostomy was performed—recovery.

In 1 case gastrostomy with pyloroplasty—recovery.

In 11 cases gastroenterostomy—2 deaths.

In 1 case pyloroplasty—recovery.

TOTAL.—51 cases with 8 deaths (15.6 per cent.).

Of the 36 cases operated upon within 12 hours only 3 died.

What can we do to improve these results? These figures represent only the cases of acute perforation in which it was possible to carry out complete operation. To get the true mortality of the accident of perforation it is necessary to add the sub-acute cases, those which were too ill for anything more than mere drainage, and those which were too ill to admit of any operation. That brings me to a series of 60 cases with 16 deaths, or 26 per cent. mortality, which shows how great is our responsibility. We must get the cases to the surgeon as soon as possible, as the time which elapses between perforation and operation seems to be the most important factor in ensuring success.

How does a previous history of indigestion help us? I have told you that many cases occur in which there is no history of indigestion; but when there is such a history it is a great help in diagnosis. A negative history on that point is of no value. If every case were allowed to run its natural course without interference, we should find that there was pain, shock, a period of reaction, followed by peritonitis, toxæmia, and death. In most cases the onset is sudden and severe; it may be even overwhelming, so that the patient falls down in the street. Some of the patients feel as if they had been kicked, or struck by lightning; sometimes they writhe in agony, and roll on the floor. *The shock may be only transient, but in most of these cases there is definite evidence of shock;* they may be so faint as to alarm their friends, or the medical attendant. *The testimony of friends as to the occurrence of this stage of collapse is most important.* People have been known to die in this condition of collapse. In a smaller proportion of cases the onset is less severe, and in some it is even gradual. One patient, æt. 34, said that for 24 years he had had definite stomach trouble, with pain two hours after taking food, and relieved by taking more food. But he never vomited, and the bowels were regular. During this period he had been taking medicine, which he obtained from a chemist; he had never consulted his doctor for the condition. Two weeks ago the present attack of indigestion began. On the day on which perforation took place he had dinner at twelve o'clock, and began to suffer pain at four o'clock. At five he took tea, and was at once relieved. At seven, when on his way home, the old pain returned, and got gradually worse, so that he had to walk doubled up. At 7.30 Dr. J. J. Campbell found the patient rolling in bed in an agony of pain, sweating, and looking collapsed. His abdomen was uniformly rigid. Dr. Campbell gave a ¼gr. morphia, and telephoned for me, as he diagnosed that perforation had occurred. When I saw the patient he looked well, without anything to suggest serious abdominal trouble. He not only

said the pain had disappeared, but volunteered the statement that it commenced to disappear before he had the morphia. His pulse rate was 66, and it was full. There was some rigidity in the upper segment of the right rectus, with slight tenderness, but no tenderness elsewhere. In consequence of his condition, and his statement that the improvement set in before he had the morphia, I gave my opinion that there was no perforation. But at 10.15 p.m. the pain began again, gradually, as before, and a hot poultice was applied, but at 10.45 he was sitting up in bed complaining of great pain, and his abdomen was rigid all over. He had ten grains of phenacetin and 20 drops of liq. morph., but without relief. Later on, his doctor saw him and found him looking worse. The patient was removed to the Newcastle Infirmary, and at 4.15 a.m. I saw him, when the change in his appearance was very marked. The whole of his face was grey and drawn, and his lips blue and dry. He complained of pain, and his pulse was 76. We found a ruptured duodenal ulcer, which we sutured, the man recovering. *After a period of pain and shock, there is always reaction, and this fact I wish to emphasise.* The early shock may pass off in half an hour, or it may last two or four hours. I am, of course, not referring to the improvement which comes on after the patient has had morphia. The reaction I speak of may be most striking, so that the anxiety of the friends is much relieved; and it may mislead the medical attendant. To illustrate this phase, I may quote the case of a man, æt. 37, a bank manager, who gave a history of duodenal ulcer extending over some years. He was in his garden one evening, and later went to see some friends, with whom he had supper. Immediately after the meal he was seized with most severe pain in the abdomen, which caused him to roll on the floor, and he looked as if he would die. His friends thought he must have taken poison by mistake. The abdomen was rubbed by his friends, and this gave him some ease; but the parts soon became so tender that he could not allow them to be touched. He was so bad that he could speak only in a whisper. When his doctor saw him he was cold and collapsed and was looking blanched and ill, his abdomen being very rigid. I arrived early next morning, and found the patient so much better that he said if we would leave him alone he was sure he would be able to go back to his work. He looked a good colour, like a man who has been used to life in the country. But his abdomen was rigid and tender. I found that he had a ruptured duodenal ulcer, with general extravasation. Fortunately he recovered. Other cases in the period of reaction could be quoted, such as that of a patient who was admitted to the hospital, and so far recovered from the shock which attended the onset that I was deceived, and allowed the patient to lie for two hours before I was able to make up my mind. But the persistence of tenderness and rigidity enabled me to come to a decision. In another case, seven hours after perforation the girl was so much better that it was difficult to persuade the mother that an operation was necessary. We must not be misled by what the patient is able to do in this period of reaction. These patients are sometimes able to walk a long distance from work to their lodgings before being seen by a medical man. From this stage of collapse the progress may be slow towards the establishment of peritonitis. *It is, therefore, important that you should attach grave significance to the history of the initial attack.* But the real "lethal interval" is that induced by the administration of morphia. I must quote you the case of a man, æt. 61, who said that during the whole of his life he had had stomach trouble, taking the form of pain after food, coming

on two hours after a meal. The pain was worse at night. Taking sodium bicarbonate, or lying down quietly gave him relief. At times he had twelve months of freedom from the pain. Five years ago he consulted his doctor, and had several bottles of medicine, but he has not been continuously under the care of any medical man. On Thursday morning, at 11.30, he was stooping down when he was suddenly seized with a severe pain in the upper part of the abdomen. He managed to get into the house in a doubled-up posture, and his wife noticed that he looked white and very ill. He was sweating very profusely. He was assisted to bed and a doctor sent for. At 12.30 the pain was a little better, and he had a $\frac{1}{4}$ grain morphia with atropine. Two hours later the doctor saw the patient again, and, feeling sure that perforation had occurred, sent for me. I arranged to go out by the first available train, but as I was about to leave a telegram was handed to me saying it was not now necessary for me to come. That message was prompted by the apparent great improvement in the patient. He looked well, his pulse was 80, and there was no elevation of temperature, while his pain was considerably less. At 7.30 next morning the doctor was sent for again, and was told that the patient had had a bad night, and had frequently complained of pain. At 6.30 the pain was much worse, and when the doctor saw him at 7.30 he was obviously very ill; the pulse was alarmingly rapid and weak. I went out by the next train, and saw the patient twenty-four hours after the perforation. I found a big man lying in bed, on his left side, moaning with pain, his face grey, lips blue, and a pulse of 142, and almost imperceptible. His tongue was dirty, but not dry. His abdomen was rigid, but not distended. Nothing could then be done for him, and he died a few hours after I saw him.

With regard to physical signs, *rigidity is of the greatest possible importance*, and it is scarcely ever absent in these cases. It is characteristic for these patients to come in with their abdomen very hard; indeed, our house-surgeons have come to practically diagnose the cases on this one point, combined, of course, with the typical history. It is difficult for the patient to take a deep breath, and there is tenderness all over the abdomen, though it may be more marked in the epigastrium, and even in the iliac fossa. I attach no importance to the absence of liver dulness, unless the liver area is tympanitic. Lesser degrees are not of value. Dulness in the flanks is a late sign. Observation of these cases enables one to detect a gradual increase of pulse rate, and that, with the onset and the presence of rigidity is enough for the diagnosis.

Time does not permit me to enter into details about the operation, but in the majority of cases it is simple enough. Having found and sutured the ulcer, I think it is very important to irrigate the peritoneum, and not be content with mere mopping. Give attention to Douglas' pouch, because only four hours afterwards that has been found full of fluid. It is usually unnecessary to drain the peritoneal cavity, and that leads one to ask what we can do with the desperate cases, those which have gone on so long that it is not reasonable to expect a good result from operation.

With regard to the question of temporary gastrostomy, that was brought forward, as far as I am concerned, by Mr. W. G. Richardson, one of our surgeons. I think it is most valuable. When it is necessary it is in those cases which are not seen by the surgeon for more than twelve hours after perforation, in which peritonitis has already developed, and especially has reached the upper part of the abdomen, because it

is in those cases that there may be acute dilatation of the stomach, from which the patient may die. If there has been gastrostomy, one can at once say whether there is gas in the stomach. The gas is let out, and the stomach can be washed out through the tube, giving very great relief. For cases in this late stage this has helped to diminish mortality.

We have still to discuss the question of the use of gastro-enterostomy for perforating ulcer. I will simply give you the conclusions. The question is, does the act of perforation cure the gastric or duodenal ulcer? I found that 38 per cent. of patients were not cured by the simple act of perforation, and those were the cases which gave a long antecedent history of indigestion. This is what one would expect. Therefore, I have made it a rule that where there is that long history, to—if the patient is able to stand it—do gastro-enterostomy or pyloroplasty. I went over the notes of my hospital cases and tried to determine from the histories in which it seemed that gastro-enterostomy should have been performed, and it worked out about the same—from 35 to 38 per cent., and this was further confirmed by an investigation into the after-histories. There are some circumstances in which pyloroplasty will be a simpler operation and will fulfill the same conditions as gastro-enterostomy. Those are the cases with an ulcer just at either side of the pylorus. That point, however, is a contentious one, and I have dealt with it in a recent number of "Surgery, Gynæcology, and Obstetrics."—June, 1912.

In conclusion, I desire to pay a tribute to the practitioners in the district in which I work, because it is through their help that the mortality through this calamity has become lower. I said, years ago, that the onus of making an early diagnosis rests with the practitioner, and therefore the credit belongs to him when the cases are carried to a successful issue.

ORIGINAL PAPERS.

TRACHEO-BRONCHIAL ADENOPATHY.

By PIERRE MAUREL, M.D.,

Late Interne in the Paris Hospitals, Consulting Physician at
La Bourboule.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

WE see a great many cases of tracheo-bronchial adenopathy at La Bourboule, and it may be interesting to run over the principal features of these cases and to follow them in their course in view of treatment and prognosis. The main symptoms are, of course, familiar to all: Signs of pressure on the superficial and deep veins, a pertussis-like cough, laryngeal troubles, dulness over the anterior and posterior glandular area, diminution of the vesicular murmur, interscapular vertebral bronchial soufflé, and the characteristic radiosopic appearances.

Once the diagnosis of tracheo-bronchial adenopathy is established, it remains to be settled whether the glandular affection is or is not tuberculous. Without at once employing the cuti-reaction we may look for the constitutional symptoms, which, as a rule, suffice to establish the diagnosis.

In tuberculous cases the patient is usually pale, thin, delicate, with a narrow chest. The features are drawn; the skin is dull, dry, rough; the veins are prominent, and the pilary system well developed. In the axilla, neck, and groin we find little glands that roll under the finger. This constitutes micropolyadenia, which, in the young, is an important sign of the onset of tuberculosis. The evening temperature may be raised, and when this is the

case in association with loss of flesh and anæmia we are justified in suspecting tuberculosis. One sign pointing to the tuberculous nature of the glandular enlargement is the persistence of the symptoms. Whenever the enlargement tends to become persistent suspicion should be excited. But the adenopathy is not necessarily tuberculous. This glandular enlargement may supervene after bronchopneumonia following measles, or after whooping cough, as well as after affections of the nasopharyngeal mucosa, the tonsils, the trachea or the bronchi. It is met with in influenza, typhoid fever, glandular fever, mumps, erysipelas and impetigo.

The physical signs are the same as in tuberculous adenopathy, but they are less marked and less durable; indeed, this diminished persistence is a sign of good augury.

The symptoms of inflammatory tracheo-bronchial adenopathy run a rapid course and soon subside. In mild cases of simple acute adenopathy the swelling subsides along with the cause. In other cases there is a remission, but this may be merely a stage of latent tuberculosis. After disappearing the signs may recur, and this ought at once to make us think of tuberculosis. If prolonged, the latent period may be regarded as tantamount to recovery, but bacillary foci may remain embedded in the glandular parenchyma. Acute meningitis and pulmonary tuberculosis may supervene years after apparent recovery. These long periods of quiescence do not prove the non-tuberculous nature of the adenopathy; on the contrary, they may be evidence in favour thereof.

Lastly, the symptoms, instead of disappearing, may persist. In this case, apart from the local mediastinal or pulmonary symptoms, the tendency is to acute generalised tuberculosis, chronic pulmonary tuberculosis, or cachexia. The last-named is common enough in very young children, and resembles the cachexia of gastro-intestinal affections of infancy minus the digestive disturbance. The patients may succumb to the pressure effects on the mediastinal organs or to pulmonary complications.

Should the tracheo-bronchial adenopathy be neither tuberculous nor simple, it may possibly be syphilitic, but this is much less frequent. It is met with in the secondary and tertiary periods, or it may be a symptom of inherited syphilis. The patient's history, the concomitant signs, and the existence of specific stigmata should put us on the track. The rapid and favourable effects of specific treatment will serve as the touchstone of diagnosis.

Lastly, if the adenopathy is not simple or tuberculous or syphilitic, we must consider the possibility of its being due to leukæmia, and, with this in mind, examine the blood, spleen, and other glands.

We need only mention such a thing as lymphosarcoma with its sharp pain, its rapid course, and its œdema.

In arriving at a diagnosis of tracheo-bronchial adenopathy we must also take into account such accessory factors as age, the ætiological conditions in which the affection occurred, the general health, the patient's antecedents, and the presence of manifestations in the bones, joints, skin, glands, etc. Even in apparently innocent cases we must never lose sight of the possibility—indeed, the probability—of the enlargement being tuberculous. My own experience almost leads me to agree with Baboneix that clinically tracheo-bronchial adenopathy is always tuberculous.

There is a supreme test in doubtful cases—*viz.*, the cuti-reaction.

The prognosis depends upon the nature of the glandular affection. As in most instances this is tuberculous, the outlook is necessarily grave; but, though graver, it is not necessarily fatal. This is

a curable, not very virulent, form of tuberculosis, but treatment is all important, the more so because we must always apprehend a recrudescence in spite of the appearance of recovery, which may be incomplete. It may only be a period of quiescence with the ever-present risk of generalisation. The disease does sometimes remain for a long time quite silent, and this is not compatible with health and longevity, but there is all the time a focus of bacilli which, under certain influences, may burst into flame in a form of meningitis, galloping consumption, or what not.

There is reason to believe that the most extensive adenopathies are not the most threatening, nevertheless we must look upon them with suspicion when they evince no tendency to improve, and are causing troublesome pressure symptoms in the mediastinum. Little glandular enlargements which rapidly undergo absorption appear to justify a good forecast. These are often merely congested glands, which may be absorbed or become sclerosed. The prognosis also depends upon the state of the lungs and upon the early institution of treatment. It is essential to recognise and treat the condition early. At a very early period, as Grancher points out, the condition is eminently curable—the most curable, indeed, of all chronic diseases. This is the time to send these patients to watering places where special attention is paid to the treatment of these glandular troubles, and to institute the treatment now to be discussed.

The treatment is that usually employed in presence of tuberculous lesions: the administration of arsenic in one form or another over long periods of time with periodical intervals of repose, the iodide of iron, iodotannic syrup, cod liver oil, glycerophosphate of lime, etc.

Counter-irritation to the chest—as, for instance, the repeated application of tincture of iodine, turpentine or ammonia liniments, and hydrotherapy. These patients should live in the country, for the open air is specially indicated in the torpid forms, and prolonged seaside residence. There we can apply Grancher's formula—*viz.*, a double ration of fresh air and food and half a ration of work. Sunbaths are not without value.

The food should be abundant, but must not contain too large a proportion of nitrogenous articles—indeed, it should consist mainly of farinaceous articles.

The principal point to consider is the prophylactic treatment. After whooping-cough and measles we must give the pulmonary condition our careful attention in order to obviate, as far as possible, the risk of tuberculous contamination. Then, too, we must hasten to restore the organism to a state of normal resistance as a further safeguard against bacillary infection. On the other hand, we must take all necessary precautions to avoid contamination *via* the food—as, for instance, the ingestion of the milk of tuberculous cows. I have seen very remarkable results attend a course of treatment at La Bourboule, and similar results are obtained at Challes, Eaux Bonnes, Mont Doré, etc.

CRITICAL PERIODS IN INFANT LIFE.

By J. HUGH HEANEY, M.D., B.Ch.

THE two critical periods in the nutritive life of an infant are, (1) at *birth*, in case the mother's milk does not become available, and (2) at any time that the maternal supply fails and artificial feeding becomes necessary.

The chief symptoms of indigestion at either of these periods are: wasting, constipation, or constipation alternating with diarrhoea, and vomiting. It

is of the utmost importance to treat the vomiting. With its cessation the other evil symptoms quickly ameliorate. To this end, many mixtures of varying proportions of milk and water, children's foods, condensed milk, etc., had in times past to be patiently tried.

The advent of sodium citrate was certainly a boon, and in many cases it acted wonderfully well. It is, however, said to have certain serious effects on the general health when used persistently. A good deal of practical difficulty has been found in regard to the dispensing of the small powders of sodium citrate, so that it has been necessary to have recourse to keeping the salt in solution.

During the past six months I have seen many cases belonging to the two classes referred to above. Among them were two premature infants (7-8 months) who belonged to the first class, and had received no mother's milk at all. Of the second class, one was very obstinate indeed. The baby was five months old when the mother's milk quite disappeared. The child had been ailing for some weeks, and no doubt was suffering from the use of a milk deficient in quantity and quality. The gastric irritation was intense.

The efficacy of cow's milk properly diluted and with sufficient milk albumen added to equal the percentage of that in human milk had been brought to my notice. I tried it in these cases (using Nestlé's milk instead of cow's in the premature cases) in the form of Albulactin, which claims to be pure milk albumen in the form of a sterile, soluble powder. Good results were immediate, both in the case of the newly born babies, and in the older ones in whom the maternal supply had failed. But in the one case just referred to, where the baby had been at the breast for some months, the vomiting was very persistent, but eventually yielded to the milk albumen dissolved in water alone.

The *rationale* is said to be that when the albumen content of cow's milk is increased to equal that of human milk, we get during gastric digestion the fine flaky curd of human milk, instead of the hard, firm, bulky curd of cow's milk. I believe there are chemical reasons given for that, but, at any rate, the difference is obvious to the naked eye.

The period of dentition is again critical. Convulsions are frequent, and although it is sometimes denied, there would seem to be a special tendency to bronchial ailments and various types of skin eruptions.

Careful attention to the feeding, to the hygiene of the mouth, and the judicious administration of bromides in sufficient doses to procure plenty of rest, will meet with much success. In severe cases it may even be necessary to administer small doses of chloral in order to secure adequate sleep. However serious the condition of a child may appear to be during dentition, under judicious treatment it will thrive perfectly satisfactorily.

There is another and most important critical time in infant life, which does not arise from within: I refer to the risk run in July, August and September of each year of contracting Infective Diarrhoea.

The question of prevention is most important, and in view of certain dangers arising from the use of cow's milk as at present supplied, I intend to prescribe a good brand of condensed milk with the addition of milk albumen. Condensed milk, although not absolutely sterile, seems to be less risky than cow's milk for the use of the general public (used only for the danger period). The lumpy curd of unmodified cow's or condensed milk would seem to be a suitable nesting place for bacteria. The addition of milk albumen obviates this. Hence, for the masses, the easily prepared and simple prescrip-

tion: condensed milk and a good form of milk albumen.

With regard to the treatment of the diarrhoea; I have nothing to add to what has been already well written on the subject, except that for egg albumen, milk albumen, dissolved in water might with advantage be substituted.

It is more nutritious, more easily prepared, and the water used may be either hot or cold.

DARWINISM AND MEDICINE. (a)

By HERBERT CAIGER, M.B.LOND., F.R.C.S.ENG.,

Burghersdorp, Cape Colony.

In these days of vaccines and serums, when, if I may be allowed to say so, the bacteriologist is rampant and aggressive, there is a danger lest his brilliant successes should monopolise too much of our attention. Other aspects of disease are apt to suffer from undeserved neglect. The evolution theory, for example, has most valuable practical lessons to offer to the medical practitioner. Darwinism and bacteriology may be regarded as the two greatest gifts of nineteenth century science to medicine. They grew up side by side; but while to-day the bacteriologist holds the field, the practical bearings of the evolution theory on medical work are to a great extent neglected or forgotten.

At the present time it may be taken for granted, I think, that the evolution theory has in its broad features been generally accepted by scientific men. The bitter animosity and opposition that greeted Darwin's revolutionary doctrines fifty years ago have died down. In this twentieth century we willingly admit that the useless hairs scattered over our arms and legs are the remnants of the abundant coat of hair that kept our anthropoid ancestors warm. We may further admit, without a blush, that the habit of swinging the arms when walking is just an unconscious reminder of the long distant day when our ancestors were quadrupeds, and all four limbs of necessity kept time together.

PRACTICAL AIM OF THIS PAPER.

The purpose of this paper is practical rather than speculative—namely, to consider what help the evolution theory offers us in our work as practitioners, what assistance it has to give in our efforts to cure or prevent disease. Obviously, the subject is a large one; time will only permit us to glance at a few of the suggestions arising from this interesting line of thought.

In the first place, let us single out some of the principles of Darwinism that specially concern our own species, and the problems of disease; and in the second place let us consider some practical applications.

The fundamental idea of Darwinism, as applied to man, is, of course, that the human species is descended from a long line of animal ancestors; the prehistoric savage was preceded by the ape, and the ape in turn was descended from a quadruped, and so on.

The successive stages of growth which each individual passes through, from the ovum to the mature adult, are a recapitulation in brief, an epitome, of the successive stages of the evolution of the species. Thus the human embryo in its earlier stages is very like that of other mammalian animals, and presents a perfectly definite tail.

ADAPTATION TO SPECIAL ENVIRONMENT.

Of more immediate interest for our purpose is the doctrine that the anatomy and physiology of each species is most minutely adapted to its environment and habits. This close adaptation is the outcome of the keen struggle for existence through an enormous number of succeeding generations. It follows, then, that attempts to make radical changes in the habits or environment of any highly developed species are apt to be disastrous. For every species, a long

(a) Paper read before the South African Medical Congress, at Johannesburg, April, 1912.

heredity has adjusted its organs so exactly to certain conditions, that the limits of change which nature will permit without mishap are very narrow indeed. Civilised man is continually experimenting in this direction. As our civilisation progresses, we are, perhaps all unwittingly, making ever more daring and reckless experiments in altering our environment and habits.

It would certainly seem that, during this last wonderful century of progress, our ambition has overleaped itself. Steam and electricity have revolutionised human conditions, and the prevalent physical deterioration compels us to admit that civilised man has been forcing the rate of change in his environment and mode of life beyond the limits of safety. We have deviated too much, or too rapidly, from the ways of our ancestors. Our children, and perhaps still more our grand-children, will have to pay the penalty.

WEISMANN'S THEORY.

Another modern evolutionary doctrine of great moment for us, is the non-heredity of acquired characters; that is to say, that any modification acquired by an individual during his lifetime, as the result of environment, is *not* transmitted by heredity to his children. Only individual variations or modifications that are in-born or constitutional, the outcome of some inherent peculiarity in the germ plasma, are inherited. For instance, the practice of binding the feet of Chinese girls, carried on for centuries, has not affected the shape of the feet of the new-born Chinese infant. The custom of circumcision, enforced in certain nations for thousands of years, also serves as an illustration of this law. I hope that I am right in bringing forward the modern decay of teeth as another instance. Like the more direct mutilations first mentioned, it may be produced in one generation after another by ill-advised changes in environment or habits, but it is not, let us hope, hereditary. To this question, however, I hope to return later.

LATEST ACQUIREMENTS UNSTABLE.

Another evolutionary dictum of special medical interest is that in the evolution of any species the latest acquirements are the more unstable: those structures or faculties, which have in the history of the species been most recently evolved, are the most liable to become deranged. The human brain in its present development is especially characteristic of our species. Its high development is a comparatively recent acquisition. But if the brain of man is more developed than that of the sheep, it is also more unstable. Insanity and neurasthenia are the diseases of human beings, not of lower animals. Similarly with the human hand, some of the muscles for moving the thumb are peculiar to our species; and it is, I think, these muscles and other muscles of the fore-arm concerned in fine movements of the hand, that are particularly liable to be effected by tenosynovitis, and writers' cramp. The human voice is another late acquisition of the human species. Possibly the complaint known as "clergyman's sore-throat" deserves mention in this connection. The faculty of speech and voice production involves control of a complicated nervous and muscular mechanism, which under stress is liable to get out of gear.

APPLIED DARWINISM: A THERAPEUTIC MAXIM.

Turning now to the more practical side of the question, the Darwinian doctrines we have just glanced at seem to point to a therapeutic maxim of wide applicability. It is this—that when, under civilised conditions, an organ or faculty becomes deranged, a temporary return to more primitive conditions of working will favour its restoration to normal action. In other words, when the human organism has got out of gear, harmonious working will be regained more quickly by approximating more nearly to those earlier ancestral conditions, to which long ages of heredity have so closely adapted it. That seems to be a logical deduction from what has just preceded. Do not, however, suppose that this implies a return to a state of barbarism, where clothes and cookery are unknown. So thorough-going an application of the principle is

evidently impossible. But short of such heroic measures, applying this principle in a temperate and rational manner, it may lead to valuable and practical suggestions. A careful analysis of the mode of life of our prehistoric ancestors will bring to light important factors and conditions which may be readily adopted by civilised man in the twentieth century in his efforts to prevent or cure disease.

OPEN-AIR TREATMENT.

The modern open-air treatment of consumption furnishes a most notable example of this. The treatment in vogue fifty years ago may be described as a "molly-coddling" treatment, keeping the patients too much in close rooms, avoiding above all things a draught or cold current of air. This was certainly not a return to the primitive environment of the species, but a more complete divergence from it. This old-fashioned method was no doubt in its day supported by arguments based on the physiology of the time. But it was plainly in direct opposition to the fundamental principle we are considering. The molly-coddling system is now discarded as a failure. On the other hand, I believe that the open-air treatment will prove not the mere fashion of the day, but will, as time goes on, receive ever wide application. On the broad evolutionary ground indicated above, should we not urge its employment in many other diseases? Its use in pneumonia is already becoming more widely acknowledged, and probably in the near future it will become a matter of routine in many other complaints. In our schools, too, the system of herding children together for hours daily in imperfectly ventilated rooms has obvious disadvantages. It is one cause that contributes towards physical deterioration. Why should not the system of open-air schools, now adopted in a few instances for tuberculous children, be universally adopted for the public schools of the future?

SEDENTARY LIFE UNNATURAL.

Passing on from the respiratory to the circulatory system, there are two points to be briefly noted. Our prehistoric ancestors led a very active life: no food without exercise was the order of the day. To obtain food, and to escape from enemies, would in the keen struggle for existence involve a life of constant exercise. The circulatory system, in its anatomy and physiology, is adjusted to meet the requirements of an active, not a sedentary animal. One essential condition of a normal circulation of the blood, and still more of the lymph in many parts of the body, is that the adjacent muscles should be frequently called into action. Under civilised conditions the comparative absence of muscular contractions and relaxations leads to a feeble, sluggish circulation in certain parts of the body. This seems, perhaps, so self-evident a fact that it is unnecessary to call attention to it; but its importance is too commonly overlooked. The difference between a vigorous and feeble circulation in any part of the body may make all the difference between success and failure in resisting a local invasion by micro-organisms. The blood may be rich enough in opsonins and antibodies, but if the local circulation is feeble the tissues may not be supplied with a sufficient amount of these substances to resist the attacking microbes.

EXERCISE AND CIRCULATION.

Let us consider briefly three illustrations of the operation of this law. First, in the pharynx and nasopharynx: the circulation of lymph and blood here depends very greatly on the activity of the surrounding muscles, the pterygoids and other muscles of mastication. Prehistoric man was compelled to bring these muscles into frequent and vigorous action, else he must starve. In modern times, cookery and milling machinery have relieved these muscles of 75 per cent. of their normal activity, especially in young children. The natural consequence has been a feeble and sluggish circulation, inadequate to ensure a healthy state of the local tissues. Hence come adenoids, nasopharyngeal catarrh, and chronic hypertrophy of the tonsils, with all the evils that follow in their train.

LUMBAGO.

Let us apply the same line of argument to another common complaint—lumbago. The muscles of the back, in the days of our barbarian ancestors, would be kept constantly exercised by the frequent necessity of stooping to search for food in or on the ground. The vascular supply of these muscles was developed to suit this condition of vigorous activity. In civilised days many of us seldom, if at all, call these muscles into vigorous action. The circulation of lymph and blood in the loins becomes sluggish and inadequate, so that the muscles of that region are specially liable to be affected by the toxin or other agent that is the exciting cause of lumbago. The practical moral of this is, that after a patient has recovered from an attack of lumbago, he should be induced to devote five minutes every day to bending exercises, which, by bringing about a more vigorous circulation in the affected muscles, may render them less liable to a recurrence of the attack.

JOINT AFFECTIONS.

A similar line of reasoning may be applied in regard to many cases of mild chronic rheumatism affecting single joints, for example the knee or shoulder. One essential factor that needs to be remedied in such cases is the feeble circulation in the joint tissues, due to an absence of those full and frequent movements of the joint, which were inevitable in prehistoric days, but which are no longer enforced by the circumstances of the present day. The knee, for instance, is rarely completely flexed by the modern sedentary person; whereas, in primitive times, the natural crouching posture adopted in defæcation and at other times would involve complete flexion of the knee-joints on frequently recurring occasions.

GRAVITATION: THE ERECT POSITION.

The influence of gravitation is an important factor in the physics of the circulation. The change from the quadrupedal to the erect position obviously added fresh complications to the hydrostatic problems nature had to solve. The erect position must make the influence of gravitation much greater. The tendency to deficient blood supply in the head, and to passive congestion in the legs and pelvis, must have called for the evolution of compensation mechanisms to counteract it. Piles and varicose veins are, in a sense, the consequences of our erect position, while some writers regard neurasthenia as being essentially similar in its origin, as being due to inadequate cerebral circulation resulting from the assumption of the perpendicular position.

COMPENSATING MECHANISMS.

Professor Leonard Hill has specially studied and described the compensatory mechanisms that exist for counteracting the undesirable effects of gravitation in the human circulatory system. It is to be noted that these compensating mechanisms are comparatively recent developments in the history of our evolution. Consequently different persons present great variations in this matter. In some individuals they are far more efficient than others. Some who have been less fortunate in this respect are unusually susceptible to the influence of gravitation on the cerebral circulation, so that, although possessing sound hearts and normal vessels, they will suffer from unpleasant sensations of faintness, and confusion of ideas, merely in consequence of standing still for several minutes. This condition may be met with in a man who is to all appearance quite strong and muscular, and who is capable of walking for miles—if he walks briskly—without undue fatigue. This condition is one that it is important to recognise for several reasons. I have only seen it referred to in Dr. Harry Campbell's very interesting book on "Treatment," to which I am indebted for several of the ideas in this paper. Dr. Campbell points out that such an idiosyncrasy would have an important bearing on the kind of exercise to be prescribed for a patient; cycling and riding would be most suitable; while leisurely walking, such as is usual in playing golf, is likely to be less beneficial. In the choice of a career, also, such an idiosyncrasy

may be of importance. A medical student so afflicted would be well advised to devote himself to medicine rather than surgery, as it might seriously handicap him in performing surgical operations.

EYESTRAIN AND NEURASTHENIA.

With regard to affections of the nervous system, time will not permit of more than briefly touching on one or two points. In recent years eyestrain has come to be an important factor, frequently met with in the cases we have to deal with. In primitive times the human eye would be used chiefly for distant vision. The ocular muscles would be comparatively seldom called on to fix and focus objects nearer than eighteen or twenty inches. The constant strain involved in reading small print at a distance of ten or twelve inches or less for six or eight hours a day would be utterly foreign to the experience of primitive man. It is not surprising that the nervous strain involved in such a fine adjustment of the internal and external muscles of the eye should lead to headache and other nervous troubles if the effort is further complicated by astigmatism. That headaches may be the result of eyestrain has now become widely recognised. What is not yet so generally known is that neurasthenic symptoms and dyspepsia in many cases have a similar origin. In those cases commonly spoken of as "nervous breakdown," especially in students or others whose occupation involves much near work for the eyes, the possibility of unsuspected eyestrain being the cause of the trouble should always be borne in mind. Otherwise much valuable time may be wasted in rest cures, sea voyages, etc., when what is needed is suitable spectacles. Very slight degrees of astigmatism are enough to cause severe symptoms, and there may be no symptoms to attract attention specially to the eyes. In cases of dyspepsia, too, as Campbell points out, where none of the usual dietetic errors are present, astigmatism may prove to be the cause. My own experience confirms this. As bearing on nervous affections, we may notice in passing that the mental conditions of our ancestors before the dawn of civilisation included, among other things, a complete and blissful ignorance of their own internal anatomy. Their women-folk did not worry themselves into a hysterical or neurasthenic state because Dr. A. had told them the womb was out of place, or Dr. B. had said that they had a movable kidney! In many cases of movable kidney, indeed, the most important point in treatment is *not* to tell the patient of its existence. That is the statement of at least one reliable and modern textbook of medicine, which I heartily endorse. It applies perhaps with even more force to many cases of retroverted uterus, which cause no symptoms, but are discovered on making a vaginal examination.

PRIMÆVAL FOOD CONDITIONS.

Last, but not least, the alimentary system claims our attention. It is here, indeed, that the lessons of Darwinism are most obvious, most interesting, and most important. Let us review rapidly the dietetic conditions of the primæval man, going back to a period before family and social life were reached, before man had learned to herd sheep or cattle, or to grow corn. The contrast with modern times will be striking. To begin with, there was this stringent law governing food supply—no food could be had without exercise. Each and every meal depended for quality and quantity on the efforts of the individual concerned, whether man, woman or child. The only exception to this rigorous law would be the infant still under its mother's care. For young and old alike a satisfying meal would involve, as a preliminary, possibly a walk of several miles, a fatiguing hunt, or a good deal of tree climbing or digging for roots. This, then, was the first fundamental condition—no food without exercise. How would this affect individuals at different ages? We may safely infer that, in the keen struggle for existence, with barely enough food available for all, those in the prime of life would come off best, thanks to their superior strength and endurance. The child on the one hand, and the elderly person, male or female, on the other, would not fare so well. Obese

old men and women, and obese young children, though common enough in our midst, would be conspicuous by their absence in those ancient days.

HYGIENE OF OLD AGE.

As regards old age, it is instructive to notice how Darwinism confirms the teaching of two eminent physicians of our own times, who themselves reached very advanced years. Dr. George Keith, of Edinburgh, who lived to be over ninety years of age, wrote strongly advocating a spare diet after middle age was passed. With dry humour he points out that the famous physician, whose teaching was largely responsible for the vogue of the feeding-up system so fashionable in the latter part of the nineteenth century, died himself from liver disease "at the comparatively early age of fifty-eight." Sir Herman Weber, of London, who is, I rejoice, still enjoying a hale and hearty old age, has published in book form a lecture given some years ago on the means for the prolongation of life. He preaches and practises the continuance of active exercise in old age, advising a *daily* walk of six or seven miles in all weathers, with a walk of twice that length once a week. From what has preceded, it is clear that a spare diet, combined with regular and abundant exercise, would be the rule of life for grandfathers and grandmothers in the days of old. Advancing age would probably involve for them as great labour in gathering the daily ration as in the days of their prime, while the food actually obtained would be less. Such were the conditions to which the alimentary system of those past their prime was adapted through countless past generations. Darwinism would thus seem to confirm the statement made by Sir Henry Thompson in his "Food and Feeding," that those devoted daughters who insist on keeping their old people at home in arm-chairs and feeding them up with additional nourishment are really hurrying them to their graves!

FASTS BY FORCE OF CIRCUMSTANCES.

Passing on to another point of interest in primæval dietetics, it may be surmised that complete fasts, of longer or shorter duration, would be of common occurrence. Circumstances would often arise—such as bad weather, pursuit by dangerous enemies, human or otherwise—which would make it impossible to obtain food for a time. Our primæval ancestors must have often gone entirely without food for periods of half a day, or even for one or two days, while occasions on which only half rations were obtainable would be more frequent still. Certainly three square meals, on each of the three hundred and sixty-five days of the year, would never be the experience of any of them, so keen was the struggle for existence then. If we assume, therefore, that these were the conditions under which our ancestors lived up to the comparatively recent times when civilisation began, it follows that the alimentary system of our species is by nature adapted to these conditions. It is difficult to escape the conclusion, however unwelcome it may be, that an occasional fast may be a useful therapeutic measure. Indeed, there are, I think, enough data to hand from other sources to convince us that fasting as a therapeutic measure is deserving of serious consideration. The therapeutics of fasting should be thoroughly and scientifically investigated. Experiments on animals have shown that a fast produces an astonishing diminution in the number of micro-organisms in the alimentary canal. Clinical experience has proved the immense value of a fast of twenty-four hours' duration in the treatment of infantile diarrhœa, only water being given. At the 1910 meeting of the British Medical Association, Dr. Guelpa, of Paris, read an interesting paper, quoting some cases of remarkable improvement in diabetes and toxæmia as a result of repeated fasts of two or three days' duration. The pity is that fasting as a therapeutic agent has hitherto been advocated mostly by more or less unscientific cranks. The time has come when the whole subject should be put on a rational and scientific basis. In these days, when appendicitis and other diseases arising from an abnormal degree of sepsis in the bowel are so

common, the possible usefulness of this Darwinian mode of treatment is sufficiently obvious.

OCCASIONAL FEASTS.

But the picture of primitive conditions just depicted is rather one-sided. Let us be fair, and admit that, though days of fasting and scanty meals were common, there would also be days of feasting. On rare, red-letter days, an abundance of food would be enjoyed, thanks to the success of the hunter, or through some lucky find of wild fruit in unusual profusion. I will not, however, take up time in discussing the therapeutic value of feasting. The popularity of the banquet at each of our Medical Congresses bears witness to the fact that we all appreciate sufficiently the virtue of an *occasional* feast.

MILK AND SUGAR NOT IN USE.

Turning for a moment to the articles of food available for our ancestors, there are at least three, which the modern housewife considers indispensable, which are entirely absent from the primæval dietary, namely cow's milk, butter and sugar in its present concentrated form. Milk feeding of invalids is at times much overdone. In infantile diarrhœa we have already discarded cow's milk. In enteric fever it has come to be regarded with less confidence and more suspicion than formerly. Milk is certainly not an article of diet to which the adult digestive organs were accustomed in primæval times. I would suggest a little healthy scepticism as to its value in some other diseases, where we have been in the habit of advising it.

The tremendous quantities of jam and manufactured sugar consumed nowadays are also quite at variance with Darwinian indications. The wholesomeness of sugar in its natural state in fruits, sugar cane or sweet roots, is no argument for its use in reckless fashion in the shape of the concentrated manufactured article. Trade statistics prove its consumption per head to have increased enormously in the last fifty years.

NO FEEDING WITHOUT MASTICATION.

Let us next turn to another of the fundamental laws of primæval nutrition which may be summed up in the words "no feeding without mastication." The coarse, raw, vegetable foods, on which our ancestors largely depended, would require very laborious mastication before they would yield up their starch and other nutritive ingredients to the digestive juices. In those days anyone who habitually bolted his food would starve; existence depended on thorough mastication. We have altered that: cookery and milling machinery in our day do most of the work of breaking up and softening starchy foods, which had to be done formerly in the mouths of our ancestors.

It is just beginning to dawn on us that this refinement of food, and consequent neglect of mastication, have been carried too far. The divergence from ancestral physiological conditions has been too great or too rapid. It is realised now that mastication is essential and necessary for other purposes than the softening and breaking up of hard food, so essential indeed as almost to justify the aphorism that a civilisation which neglects mastication is doomed.

CAMBRIDGE EXPERIMENTS ON MASTICATION.

Sir Michael Foster some years ago had some experiments carried out under his supervision at Cambridge University on the very thorough mastication of food. For some weeks some medical men and other observers made a practice of subjecting their food to an unusually thorough and prolonged mastication. Sir Michael Foster reported, as the result of their observations, that there was a general increase in the sense of well-being and the working powers of these gentlemen, while a marked change in the waste products of the bowel was noticed; the motions became odourless and inoffensive, suggesting that the bowel was in a healthier and more aseptic condition than is usual.

DARWINISM AND DENTAL DETERIORATION.

I have left to the last one most practical application of Darwinism, one which demands serious attention in the present day. The prevalent decay of the teeth of the rising generation has become a national evil. At the meeting of the British Medical Association, held

last year at Birmingham, a special conjoint meeting of the Dental and Public Health Sections was arranged to discuss the subject of dental caries from a public health point of view. Some alarming statistics as to the prevalence of dental decay among English children were brought forward. In South Africa things seem to be rapidly progressing in the same direction. Let us consider the matter briefly from the Darwinian point of view. The first question to be settled is whether the cause of the change is to be found in the heredity or in the environment and habits of modern children.

The view was, I believe, advanced formerly that the chief factor at work was a diminution of the size of the human jaw, due to hereditary causes. It was argued that in the slow progress of evolution, the jaw was, for some occult reason, growing smaller. If that view were the true one, the outlook would be hopeless indeed: anything that we could do would be of little avail to mend matters. That view, however, appears now to be discarded. From the very interesting discussion at the Birmingham meeting it would seem that our dental experts are becoming increasingly convinced that the main cause lies in the environment—that is to say, in the character of the food of the modern civilised child.

EVIDENCE FROM SOUTH AFRICA—LOCATION NATIVES

Here in South Africa we have some striking evidence that an altered environment may in one or two generations, produce serious deterioration of the teeth. I recently made a hurried inspection of the teeth of forty-five children in one of the native schools of the Burghersdorp Location. Ten children presented more or less evidence of dental caries detected readily at a glance. Two children only, about five or six years old, had each three or four badly-decayed teeth. What first called my attention to this aspect of the question was being asked some years ago to extract three badly-decayed teeth (permanent molars) from a native youth of fourteen, the son of a native interpreter in a Government office. This youth had grown up in the Burghersdorp Native Location. Probably in his educated father's house more or less civilised foods were used, and I suppose that these, with the consequent neglect of mastication were probably largely responsible for the woeful state of the son's teeth.

DR. HARRY CAMPBELL'S OUT-PATIENT.

It is instructive to compare with this case one mentioned by Dr. Harry Campbell in an article on mastication published in the *Lancet* some years ago. Among his out-patients at a London hospital he noticed a man of fifty with a complete set of good teeth. Such a thing was so exceptional in a London middle-aged out-patient, that inquiry was made as to the man's habits. He was, he said, peculiar in this way, that he could not swallow his food unless he first chewed it very thoroughly. He was given a moderate-sized piece of bread, and asked to eat it in his usual way. It was found that he subjected it to one hundred and twenty separate bites before swallowing it. Here, then, we have a man whose masticatory instinct had not been weakened in the usual way in early childhood, but had in some way retained full activity. Although this man had for thirty years lived in London on the same kind of food as the average poor Londoner, at fifty years of age, instead of the usual picture of a mouth full of decayed teeth in unhealthy gums, he presented a full set of sound teeth set in healthy gums.

These two cases confirm, each in its own way, the view that environment and habits are the factors responsible for dental decay for the most part, rather than any hereditary factor. Like the mutilated feet of Chinese girls, dental caries is a defect produced anew in each successive generation, produced probably by faulty methods of feedings.

AN AGE OF PAP.

The contrast in diet that has been sketched between modern and primæval times is, as a matter of fact, most marked in early childhood, probably in the case of children from one to three years old. As Dr. Campbell says, this is the age of pap. For a generation we have instructed mothers to feed their little

children, after weaning, on soft foods requiring no mastication—Mellin's Food and its congeners, milk pudding, bread and milk, porridge, mashed potato, and so on. In the discussion at Birmingham Dr. Sim Wallace spoke of such foods as "unhygienic." Certain it is that this dietary of soft foods, like the outworn molty-coddling treatment of phthisis, is *not* a return to primitive conditions of physiological working, but a divergence therefrom. Is it not a humorous position of things, that a generation of medical teachers, professed evolutionists, should have been so blind to the true bearings of the case, and refused adequate exercise to the jaws of the growing child. We might have guessed that as soon as Nature provided the young of our own species with teeth, those teeth are intended to be used. The penalties of disuse have been serious. In this respect a change in the direction of primitive conditions is urgently called for.

EVIL EFFECTS OF PAP-FEEDING.

Expert dental opinion, as expressed in the discussion at Birmingham, brings a very serious indictment against the present fashionable system of soft foods for toddlers. It does serious injury to the child in at least three ways. First, it fails to call the child's masticatory instinct into normal healthy activity. Secondly, it cheats the muscles of the jaw and tongue of their natural exercise, necessary for their proper development; the result is that the jaw and nasal passages are stunted in their growth. Thirdly, it leads to soft and semi-liquid foods remaining clinging about the teeth without having been chewed, and therefore without being mixed with their due complement of saliva. This condition favours acid fermentation, and therefore also dental caries.

INDICATIONS OF CHANGE IN MEDICAL OPINION.

A revolution of our mode of feeding young children is urgently called for. Dr. Wheatley, Medical Officer for Health for Shropshire, who opened the discussion, laid down these rules for the guidance of mothers in the future:—All starchy food should be given in a form compelling mastication, such as crusts, crisp toast, rusks, etc. No starchy food should be given in the semi-liquid form, as is so commonly done now. It is useless to tell children to masticate their food if no food is given that compels mastication.

This most recent phase of medical opinion is clearly in close agreement with the principles deduced from Darwinian data in this paper. An unused jaw means a jaw with sluggish circulation, and therefore with unsound development of teeth. More than one speaker, in the discussion at Birmingham, emphasised the fact that, for the preservation of the teeth, the character of the food was of far greater importance than the use of the tooth-brush and antiseptic mouth washes. The subject is becoming one of national importance in South Africa as well as in England. The inferences drawn from the teachings of the evolutionists in this connection appear so obvious that their neglect in the past is a matter of surprise.

Before leaving this question of dental caries, it may prevent misconception to add, that this paper does not attempt to deal in any sense exhaustively with it. Only two or three points have been touched on, because they clearly come within the scope of this paper. These are—and their importance is such as to justify repetition—firstly, that the main cause is to be sought in the character of the food supplied to our children, not in any hereditary factor; secondly, that the jaws and teeth cannot be expected to develop normally, if the natural exercise involved in mastication is not allowed due influence. The excessive use of jam and sugar in various forms, to which allusion was made in an earlier part of this paper, is also blamed by dental authorities for its effects in damaging the teeth.

CONCLUSION.

In concluding these somewhat discursive remarks, I would urge that the line of thought here suggested may often prove of service in dealing with many other aspects of disease. Darwinism, applied in a reasonable and temperate manner, may sometimes furnish sounder guidance in treatment than the latest theories of experimental physiology.

CLINICAL RECORDS.

CASES SHOWN AT THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT LIVERPOOL IN THE SECTION OF DERMATOLOGY.

DR. STOFFORD-TAYLOR and Dr. R. W. MACKENNA showed between thirty and forty cases, the most interesting of which were the following:—

DEMONSTRATION OF CASES.

1. A boy, *æt.* 14, suffering from incipient Pityriasis rubra pilaris. The evolution of the eruption, which had lasted for two years, was not yet complete, but on the palms of the hands, which were of a dull red colour, there was much thickening of the skin. Over the elbows and knees there were patches which suggested psoriasis, but on examination the scales were seen to be of a somewhat different type to the scales of psoriasis, and at the margins were seen crops of cone-shaped horny papules at the orifices of the hair follicles. The scalp and face were also slightly affected with dry scales.

2. A case of *Nævus lymphaticus* on the neck in a young girl. This case excited much interest because of its rarity.

3. A very extensive case of *Lupus exfoliatus* and follicular lupus in a man, *æt.* 42. The duration of the affection was about five years, and the parts chiefly affected were the trunk and legs. The arms, in addition to showing many tubercular deposits in the skin, had several hard subcutaneous nodules apparently attached to the muscle and tendon sheaths. A microscopical examination showed these nodules to be tubercular.

4. Six cases of *Lupus erythematosus*, in none of which was there any tubercular history. In two the affection was most severe on the scalp, and in one, besides the skin, the mucous membrane of the lower eyelid and the upper lip was involved.

5. A case of *Lupus vulgaris* on the cheek, which had been treated with zinc ions. A photograph of the patient before treatment was also exhibited, and the great improvement and the fine scar were distinctly visible.

6. A very extensive case of *Lupus verrucosus* in a girl, *æt.* 22. The eruption had affected both hands and both arms. It had been treated with zinc ions, and was completely cured. The fine scar, soft and pliable, was generally commented upon.

7. A case of *Lupus vulgaris*, affecting the outside and inside of the nose. The hard palate was also involved.

8. A case of *Lupus pernio* in a man, *æt.* 32. The ears, hands, and feet were chiefly affected, and the disease had produced considerable destruction of the ears. Treatment by means of inhalation of oxygen had been suggested.

9. Two cases to show the method in use at the Liverpool Skin Hospital for dressing children suffering from eczema of the scalp and face. The method consists in spreading the ointment or paste which is to be used on lint which has first been soaked in cold water. The face of the paste or ointment is covered with fine muslin to prevent too close adhesion to the skin and to facilitate drainage. The dressings are held in place by means of specially knitted nets, and are cool and very effective.

10. A case of Recurrent papulo-vesicular Eczema in a man *æt.* 38. This patient was shown to illustrate Dr. David Walsh's paper on the association of recurrent affections of the skin with cardiac lesions. The man has had a recurrent eruption, which has appeared at the height of the hot season each year for the past four or five years. On auscultation he was found to have an aortic obstructive murmur with some regurgitation through his mitral valve. He was quite unaware of any heart trouble.

11. A case of *Erythrodermie pityriasique en plaques disseminées* in a young man. The condition has persisted for several years, and affects chiefly the arms and trunk. It is characterised by little round or oval yellowish-red patches, which are slightly scaly. There is no infiltration. The eruption can be removed by the use of chrysarobin, which is the only remedy

which seems to affect it, but it recurs again within a week of the cessation of treatment.

12. A case of *Lichen pilaris* in a lad. The condition has persisted for two years. There were no subjective symptoms. The lesions consisted of patches of fine spines, projecting from the pilo-sebaceous orifices, and were distributed in the limbs and trunk.

13. A severe case of *Zerodermia* in a young woman. The condition was universal. The patient is the only member of the family affected.

Dr. SAVATARD showed: (1) A case of Follicular lupus in a woman, *æt.* 25. About three and a half years ago patient suffered from an acute inflammation of the bridge of the nose. The nasal passage was not obstructed. After the inflammation subsided a rash broke out gradually on the face and had remained in a stationary condition up to her coming to the Manchester and Salford Skin Hospital in September, 1911. There were at that time on the face numerous discrete apple-jelly coloured lesions—not raised above the skin surface—irregularly circular in outline and 1—3 inches in diameter, many of which showed central pin-point necrosis. Several had involuted, leaving small depressed scars simulating acne pitting. There was no evidence of any coccogenic infection. The lesions were most numerous over the bridge of the nose, extending upwards between the eyebrows to the forehead, and some few on the cheeks and chin.

2. A woman, *æt.* 25, with primary *Lupus vulgaris* of the scalp (treated by tuberculin ointment) with Tuberculous Elephantiasis of the left leg.

3. A woman, *æt.* 23, with Pendulous neurofibromata of the right leg, appearing in infancy, with smaller scattered neurofibromata of recent origin on the trunk and innumerable *café au lait* patches over the whole body.

4. Man, *æt.* 27. In April, 1911, patient was taken acutely ill. His face, trunk, and limbs were swollen. Three weeks later he saw Dr. Stopford-Taylor at Liverpool. After three months the excessive scaling disappeared and his general condition was much improved. The skin, however, remained rough. It was fairly well up to the early part of this year when he had a relapse and again visited Liverpool, but as he became progressively worse he came to Manchester and was admitted to the Manchester and Salford Skin Hospital on April 18th, 1912. On admission he had what was apparently an extensive seborrhœic dermatitis. There was considerable branny desquamation but no flaking. There was no rise of temperature nor any subjective symptoms except the feeling of *malaise*. The urine was normal. After a week's treatment with a mild sulphur ointment there was very considerable improvement and the patient said he felt quite well. Since then the eruption has almost entirely cleared only to return again, though treatment has been continued. About a month ago his condition showed a widespread desquamating dermatitis—papular in character, non-follicular—the papules are flat-topped but slightly raised above the surface of the skin and well marked on the backs of the hands. They are also evident on the scalp, trunk and extremities, with areas from which the eruption had cleared leaving the normal skin markings much exaggerated. The exhibitor considered the case one of Exfoliative Dermatitis.

5. Youth, *æt.* 19. Monilithrix, or beaded hair. The condition is limited to the hairs of the scalp, and began two years ago. It is most marked in the frontal and occipital regions, where the hairs are broken off, leaving short, beaded stumps. Many of the longer hairs, which appear normal, are also seen to be affected on closer examination. On staining no micro-organisms can be detected. There is some keratosis of the follicles and in the occipital area well-marked perifollicular inflammation is present. There is pain and irritation of the scalp, otherwise the patient's health is good.

STOKESLEY RURAL DISTRICT COUNCIL has agreed to take part in a conference called by the Thirsk Rural District Council to consider a scheme to appoint a whole-time Medical Officer for certain combined rural areas.

OPERATING THEATRES.

BOLINGBROKE HOSPITAL.

TRAUMATIC RUPTURE OF THE LIVER.—MR. SWAINSON operated on a man, *æt.* about 25, who two or three hours previously had been run over by a heavy tip-up cart, which was empty at the time. The wheel had passed transversely over the epigastric zone of his abdomen. When seen he was lying on his back in bed, respiration somewhat hurried and *alæ nasi* working; the face was rather pale, but did not show great anxiety. On examining the abdomen, there were practically no movements of abdominal respiration, the recti above the umbilicus being held and feeling quite rigid. The patient complained of some epigastric pain, and tenderness was present in this situation. Below the umbilicus, however, there was no tenderness, and rigidity, though present, was not marked. There was nothing very remarkable about the pulse, the rate being 85, the beat not irregular but somewhat feeble. The temperature was normal, and had been sub-normal on admission. There was no vomiting. The abdomen was slightly tumid, but there was no marked distension. Thus the patient might be said to be suffering from slight shock, the only positive symptom besides pain being marked rigidity. Further, as before remarked, there was a distinct history of severe injury. Under these circumstances it was decided to explore the abdomen.

An incision was made in the epigastric region very slightly to the left of the middle line, reaching just below the level of the umbilicus. On cutting through the peritoneum some blood escaped, the appearances being, in fact, exactly similar to those found in operating on a ruptured ectopic gestation. The hand was passed down to the neighbourhood of the spleen, and by palpation and inspection it was ascertained that this organ was free from damage. On mopping up the blood with large, dry, sterile abdominal sponges, the left lobe of the liver also appeared to be free from damage. The hand was now passed down to the under surface of the right lobe of the liver, and a deep rent was found in it, into which four fingers of the hand could easily be passed. This was plugged temporarily by a large abdominal sponge, and a transverse incision about six inches long was made just below the middle of the first incision at right angles to it, so that a flap could be turned up. The rent in the liver was now plugged with a long roll of gauze, the end of which was left hanging out of the right extremity of the transverse incision. No alimentary contents or mucous membrane was seen on hurriedly examining the abdominal viscera. The abdomen was sponged dry with large swabs, and the wound quickly closed, except where the gauze had been brought out, by interrupted sutures passing through all the layers of the abdominal wall. The patient was put to bed, and saline solution administered continuously by the rectum.

Mr. Swainson said he wished to emphasise the importance of exploring these cases early if there were a reasonable suspicion of abdominal injury. Abdominal injuries resemble each other very closely in their early stages, and early operation was much more likely to be successful than late. Incidentally, he said the same remark applied to the acute abdominal conditions arising from disease, such as the perforations and the acute inflammations. He had already mentioned the presence of extreme rigidity in this case. He considered rigidity the most important sign in acute abdominal cases, because it was manifested early when shock and alteration of the pulse might be absent. It was quite true that it was not always easy to distinguish pathological rigidity from that form of rigidity which patients manifested when nervous; this could be partly discounted by experience and by examining the case quietly and soothingly with warm hands. Some cases of colic also gave rise to rigidity, but here the history and the nature of the pain were helpful in arriving at a diagnosis. Next to rigidity, perhaps, the pulse was the most important thing: a pulse-rate

steadily rising to 120 or so was very suggestive of an abdominal catastrophe. Shock, he remarked, was a very important symptom, but severe shock could be present in the absence of a gross lesion, and severe injuries, such as rupture of the intestine, were sometimes not accompanied by shock at first. Vomiting was an equivocal symptom, but was suggestive of abdominal mischief. The Hippocratic facies, when present, was also important, but it might be absent. Sudden and intense pain was a very important symptom. Progressive pallor, sweating and restlessness were signs suggestive of severe hæmorrhage.

GERMANY.

Berlin, Aug. 31st, 1912.

TISSEU CHANGES PRODUCED BY THE ACTION OF RADIOTHORIUM.

THIS subject has been recently investigated by, amongst others, Dr. Prado Pagle in the Experimental Biological Department of the Pathological Institute of the University of Berlin. In his report of the investigations Dr. Pagle first recapitulates some of the results arrived at by other inquirers. By the labours of Hertwig he says proof has been found that by irradiation of eggs by the rays of mesothorium the same effect is on the whole that produced by irradiation by radium. Bickel, in raying experiments on himself, found that the rays produced first reddening of the skin, later the production of an ulcer, with subsequent cicatrisation. In these experiments, only the *b* and *g* rays could have had any effect, as the mesothorium was enclosed in a metal capsule under a mica plate. It was, therefore, certain that the *b* and *g* rays set up changes that were partly of a productive and partly of a regressive nature.

The question arose whether the alpha rays could also cause tissue changes, whether in particular the products of tissue change of mesothorium which emitted principally *a* rays had any action. The first decomposition product of mesothorium was radiothorium, which had a mean life of 1,063 days, and emitted *a* rays. The further decomposition product was thorium X with a mean life of 5.85 days; it produced *a* and *b* rays. The gas producing emanation from thorium X with a half decomposition period of only 53 seconds emitted *a* rays only.

At the request of Hr. Bickel the following experiments were made: Small deposits of an insoluble combination of radiothorium were placed under the skin of mice, and were allowed to remain there for some time, the animals were then killed, and the parts subjected to careful microscopic examination. For control purposes he injected charcoal into other mice in a similar manner.

Without going into the details of the experiments the general results were to the effect that radiothorium had an undoubted active effect when brought into close contact with tissues. Every experiment made gave proof of this. The charcoal injected into the control animals set up no reaction whatever. During the first few days the radiothorium set up a real inflammation: capillary dilatation, exudation, leucocytary infiltration. No trace whatever, after most careful search, of any micro-organisms was to be found. After a more prolonged action of the radiothorium there was caryolysis, necrosis, and increase of the fibro-blasts. The particles of radiothorium, which were numerous and large during the first few days after the injection, became gradually fewer and smaller, in some parts they were absent altogether, and in their place were only fibro-blasts and connective tissue in the form of round patches, in which the original particles of radiothorium were embedded. In the course of time these also became quite absorbed. Finally, the necrotic particles were also absorbed, and out of the fibro-blasts fibres of con-

nective tissue were formed which at last terminated in cicatricial tissue.

At the Verein f. innere Medizin and Kinderheilkunde, Herren Meyer and Schmitz related the subject of their experiences in experimenting on the

NATURE OF THE TUBERCULIN REACTION.

The theory of the action of tuberculin had been the subject of an extraordinary amount of discussion, but the last word had not yet been said. Koch held the view that tuberculin was of a toxic nature, that it set up necroses both in healthy and tuberculous individuals, but that it acted most profoundly in tissues that were tuberculous. This was also the view of Ehrlich. Wassermann placed the matter on a serological basis. He assumed that in a tuberculous centre both tuberculin and anti-tuberculin were present, that by the introduction of tuberculin into the system the anti-tuberculin combined with the tuberculin, and that a digesting and destructive process was set up by the resulting complement. This theory had been further elaborated by Citron, who had introduced receptors. Then there was the Woolf-Eisner theory of lysis.

The aim of the investigators had been to determine what the substance was that reacted with the tuberculin. For their purposes they made use of bovine tubercle in rabbits that were infected by that form. If the blood serum of animals infected with bovine tuberculous was allowed to stand 24 hours mixed with bovine tubercle and then injected into healthy animals, these became ill with considerable rises of temperature and other symptoms of disease. The serum from animals with advanced tuberculous acted the best. A still stronger reaction was obtained, when washed blood corpuscles were made use of instead of serum. Defibrinated blood acted in the same way when brought into contact with tuberculin. Also when the washed blood corpuscles of tuberculous animals were allowed to react with tuberculin and saline solution, and the mixture was then centrifugated so as to again separate the saline solution, and this was injected into healthy animals, these also suffered from rises of temperature. This, however, never took place when the blood of healthy animals was made use of. If animals had once reacted strongly after injection with tuberculous serum the reaction was weaker on further injection. If, however, the reaction was at first weak there was a stronger reaction after the second injection. Heating above 65° C. did not destroy the bodies that allowed the reaction.

These experiments therefore showed that a substance circulated in the blood of an infected animal, combined for the greater part with the red blood corpuscles, and which, combined with tuberculin, set up symptoms of disease with a febrile reaction in healthy animals.

AUSTRIA.

Vienna, Aug. 31st, 1912.

ARTIFICIAL IMPREGNATION.

It is so often necessary and desirable where coitus fails to impregnate, that operative means have to be resorted to. The barren condition often existing in married life is due to many causes, but the primary one is to prevent the sperm from wandering into places where the potency of the spermatozoa is lost. In many cases sterility is due to the female where the uterus has been inflamed, or is displaced, and thus prevents the sperm from getting beyond the vagina. The male may also be the cause of unfruitful condition from bad health, inflammation of the genitals, infantilism, syphilis, gonorrhœa, etc. If all unhealthy conditions in the male are absent it is easy to produce pregnancy by mechanical or operative means by conducting the sperm carefully into the uterus. Slight inflammation of the uterus or adnexa will not prevent a successful experiment. An undeveloped uterus or vaulted vagina should not prevent the performance of the operation, but a healthy sperm is necessary for success, and should be carefully examined with the microscope for the products of gonorrhœa. Hirsch has found the following *technique* the most successful. The sperm is first obtained from

the "condum" with a dry sterilised Braun's syringe, avoiding as much as possible any other fluid, so as not to disturb or weaken the spermatozoa. Warming the syringe to 38° C. is necessary, and this must be done carefully by a metal plate heated at one end by a spirit lamp, as the spermatozoon is very sensitive to heat and cold, and must be maintained at a constant temperature. Another important point in the operation is the entrance of the syringe into the portio of the uterus, taking care not to wound the mucous membrane, and small quantities of the sperm must be injected at one time, else uterine colic may be induced. Having inserted the necessary amount, the patient must lie in bed eight to twenty-four hours, and all washing of the vagina must be avoided, but a tampon should be placed at the mouth of the uterus.

THE INFLUENCE OF BENZOL ON LEUCÆMIA.

Koranyi has been using benzol in cases of leucæmia with best results. The white corpuscles disappearing in a short time or by the end of the third week with an increase of erythrocytes. It is effectual in all forms of chronic leucæmia with a reduction of the glands. Patients who have been treated ineffectually by the Röntgen rays yield readily to benzol. Small doses are useless, as 3-4 grammes must be given daily, and sometimes in stubborn cases for months. The only bad effects the treatment has is the burning in the stomach, sometimes vomiting, bronchial trouble and vertigo. The gastric disturbance may be avoided by giving it in capsule, and the vertigo by reducing the quantity in the dose. He has found it more effectual than the Röntgen or Thorium therapy.

HUNGARY.

Budapest, Sept. 1st, 1912.

At a recent meeting of the Budapest Royal Medical Society, Dr. A. Bürger read a paper on the

ÆTIOLOGY OF PROLAPSE UTERI.

Dr. Bürger advanced an interesting theory as to the causation of this condition. He related a case where in a new-born child there was complete prolapse of the vagina and uterus, degeneration and atrophy of certain groups of muscles in the lower extremities, atrophy of the pelvic floor musculature, as well as sensory paralysis of the lower limbs and the trunk as far as the upper border of the spina bifida. Bürger believes that this case will explain the cases of uterine prolapse occurring in women who have never borne children (about 3.5 per cent. of the cases). In these instances the factors usually brought forward are insufficient, such as manner of living, occupation, venereal excesses, improper nourishment, inflammations and tumours. Freund, a German gynecologist, attributes the condition to infantilism—said Bürger—others to an insufficient development of the peritoneum. In searching the literature, the reader has found 14 cases where this dislocation of the organs was already noted in a newborn child, ten of these also presented a spina bifida. He therefore sets aside the supposed influence of an infantile condition or the constitution of the peritoneum, and concludes that the association of spina bifida, atrophy of the pelvic floor muscles, and genital prolapse can be attributed to some disturbances of the sacral nerves, which results in the production of the anomalies in question. This view seems to be confirmed by instances seen in older individuals, where some injury affecting the sacral plexus is followed by not only a primary nervous disturbance, but also a secondary uterine prolapse.

GENORRHEAL PLEBITIS.

Dr. Guzman exhibited a case of this rare complication of gonorrhœa. The patient was a young man, who developed a marked phlebitis in the lesser saphenous veins about four weeks after an attack of acute gonorrhœa had apparently subsided. This gradually disappeared with the use of evaporating lotions. From a study of 26 cases thus far reported, it seems that the affection is usually present in young men during the sub-acute stage of a first attack of urethritis. In most of these cases an arthritis was also present. Varicose veins were seen in only one instance, so that this con-

dition cannot be looked upon as a predisposing factor. The saphenous vein seems to be most often involved. Pain and œdema are the main symptoms and six weeks the usual duration. Dr. Guzman believes that the infection is due to the rupture of some hitherto unrecognised focus, probably in the prostate, from which the septic material enters the venous system. The treatment is the same as that of phlebitis in other parts.

TREATMENT OF URTICARIA.

Dr. Csillag said, that acute urticaria may be caused by an irritating parasite, such as a flea or bedbug, or by some irritating plant. Frequently the eating of certain food, such as shell-fish or certain remedies, such as balsams or chloral. Treatment consists naturally of a light purgative, some intestinal antiseptic, such as salol, or benzo-naphthol, and quinine or alkalies. Low diet for a few days is necessary. For the pruritus, carbolic or evaporating lotions are necessary. The following prescription is useful:—

- R̄ Carbolic acid, pure, 2.00 gr.
- Glycerine, 50.00 gr.
- Water, 150.00 gr.

Lotions of chloral hydrate, 5 to 200, neutral dusting powders of chalk, starch, zinc oxide, with camphor finely pulverised one to two per cent. A useful ointment is:—

- R̄ Zinc oxide, 3 to 5.00 gr.
- Cocaine hydrochlorate (or menthol), 0.3 to 0.60 gr.
- Vaseline, 30.00 gr.

Hot or cold baths are not as useful as tepid baths. If the pruritus is rebellious, it is necessary to have recourse to a protecting envelope, either an application of a paste or plaster. In the grave urticaria of auto-intoxication prompt treatment by laxatives or emetics, and in case of collapse, subcutaneous injections are necessary. Œdema of the glottis is a serious danger of acute urticaria. Hot foot-baths and hot applications to the neck, hot fumigations, and the administration of ether, Hoffmann's anodyne and acetate of ammonia. In spite of this, sometimes tracheotomy is necessary. In chronic urticaria, careful dieting, forbidding the use of wine and other alcoholic beverages, acid or fermentable, or indigestible foods of any kind. Bowels should be moved by gentle laxatives. The dyspepsia, or atonic condition of the stomach is best treated with the use of absorbing powders, antiseptic or alkaline, such as charcoal, chalk, sodium bicarbonate or magnesia. Renal insufficiency may exist, or the uric acid diathesis. A definite vasomotor neurosis may be present. All of these call for definite treatment.

UNITED STATES OF AMERICA.

New York, Aug. 27th, 1912.

BUBONIC PLAGUE IN PORTO RICO AND CUBA.

BUBONIC plague has been in evidence in Porto Rico for some time and in Cuba for a few weeks. The situation in Porto Rico is somewhat serious. In San Juan there have been some forty cases reported and twenty-seven deaths. The latest account is that new cases have been reported in Porto Rico and Cuba. A Commission consisting of Col. Jefferson R. Kean, Major Frederick F. Russell, Lieutenant Fred H. Foucal, and F. Y. Howard were sent from Washington to make a thorough investigation in Porto Rico. Unofficially it was stated that while the disease seemed to have been checked in San Juan the Commission considered that it would be impossible to eradicate it until modern sanitary methods had been introduced, and especially until all the dwelling houses had been raised from the ground. The port health authorities of the United States are said to be watching the situation and taking steps calculated to keep the disease out of the country.

Something of a sensation was created by a statement issued by Dr. Juan Guiteras, Director of Sanitation of Cuba, the well-known yellow fever expert, and formerly of the U.S. army. Dr. Guiteras takes exception to a resolution introduced recently in the United States House of Representatives recommending an investigation of the sanitary condition of Cuba.

Dr. Guiteras proves by comparative figures that the health conditions in Cuba are far better than in the United States, Porto Rico, or Panama. Moreover, he brings the charge that the United States is trying to conceal the existence of the plague in San Francisco, whence, he says, is the source of Cuban infection, and he draws attention to the yellow fever epidemic of New Orleans in 1905, when, he declares, Cuba was infected in a similar way.

According to Dr. Guiteras, this is a very inopportune time for the House of Representatives to censure Cuba, inasmuch as that island has already given a lesson in promptness by frank recognition of the existence of the plague and by energetic action in meeting the situation. He is of the opinion that the United States would do well to follow this example in the cases of California and Porto Rico. Dr. Guiteras further insists that Mexico was infected with the plague through the concealment of its existence in San Francisco. Dr. Guiteras goes on to say "The Panama papers quote officials of the United States as saying that the infectious diseases in Cuba are a menace, but they have been misinformed as to the situation in Cuba. As a matter of fact, the conditions in Cuba are better than in the United States, and the United States in reality is a menace to us with its epidemics of spinal meningitis, infantile paralysis, and small-pox, which do not exist in our Republic. We are constantly in fear of small-pox infection from the United States. Moreover, the plague situation in California and Porto Rico is causing us much anxiety."

It should be said that if plague be present in San Francisco, the authorities have been remarkably successful in preventing the news thereof to leak out. In no medical or lay journal has a hint been given that bubonic plague exists in California. If such be the case, it would seem that Dr. Guiteras has a legitimate cause for his outspoken remarks.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

NEWSPAPERS AND DOCTORS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think that your quotation from *Reynolds' Newspaper* (in this week's "Current Topics") re the doctors and the Insurance Act should call for our sympathy rather than indignation, as it conclusively proves that the writer has not yet grasped the reasons why the doctors refuse to work the Act. In stating that we do so because we are only gaining 50 per cent. more than the societies paid us before the Act is to talk arrant nonsense, which will be apparent to even the casual reader. No mention is made of "picked lives or wage limit," and the 50 per cent. gained on certain clubbers will be more than lost on unsatisfactory lives, not to mention the 300 per cent. and more lost on patients who are now private patients, but who would, if we consented to work the Act, come under the Act. The other letter, "The Lunacy Act: A Strange Case," is unworthy of consideration, as the writer of it is anonymous, and, as you point out, the facts of the case are unauthenticated. Let the writer sign his name, prove the correctness of his statements, and then investigation would speedily follow. The narration of the case is merely the peg upon which the writer wishes to hang the hat, and the hat is the vilification of the members of the medical profession. The fact of the matter is this: As long as the medical profession allows itself to be sweated without complaint, so long is its nobility paraded in newspaper columns; but as soon as the members say, "We have to live, to educate our families, and to pay our way, and we demand a living wage," then newspapers of a certain type pour forth the vials of their wrath upon our devoted heads. I find that thinking people, both rich and poor, understand our attitude towards the Insurance Act, and express the hope that we shall remain united and frustrate the knavish tricks which would impoverish the profession, and instead of im

proving the health of the community would have the exactly opposite result. Time now devoted to reading would be wasted in filling up forms which would benefit nobody except the army of paid officials now being created by the present Government.

I am, Sir, yours truly,
Bedford, August 31st, 1912. S. J. Ross.

ANOTHER DOCTOR'S WIFE ON QUACK MEDICINES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is certain that the "Doctor's Wife" hailing from Birmingham, whose letter appeared in your issue of August 28th, does not stand alone. My experience tells me that there are few doctors' wives, being educated women, who do not dip more or less deeply into medical journalism. This is probably mostly the case among those, like myself, taking part in work among the poor, are brought into contact with public health questions. We do not, however, often write to the medical papers; perhaps some of us are a bit afraid of our husbands; some think, perhaps, their letters would stand no chance of publication. I agree with "A Doctor's Wife" that our knowledge, if made available, might be of value to the family practitioner, and I am not sure that it might not be an advantage if, to encourage our contributions, you would set apart a column for doctors' wives! I can add my testimony to that of "A Doctor's Wife" with regard to the evil being wrought by quack medicines mostly composed of alcohol. To put a stop to the quack medicine trade calls for a crusade. If Dr. Mary Sturge could begin with the alcoholic tonics she would not, I fancy, lack followers, and she would encourage others to attack evils equally harmful. Personally, I think the MEDICAL PRESS is to be commended for keeping this question always to the front. It is impossible, for reasons you have so often explained, to get it into the lay papers; but there are laymen of the right sort who read medical papers, and who are worth keeping informed on such matters.

Although leaving it till the end, I am not going to put the main subject of this letter in a postscript in the fashion that women are often charged with adopting. I really, in starting, intended to speak only of the harm which arises from the use of baby-quieting medicines, and to ask whether Dr. Mary Sturge, and other women doctors, could not take up this evil and expose it with a view to helping legislation against it. These evils, among the others arising from the quack medicine trade, have been fully described in your paper. Every visitor among the labouring class can bear testimony to the fact that if only by causing mothers to put confidence in them till too late, quack medicines for babies help in the killing of great numbers of the children of the poor every year.

I am, Sir, yours truly,
ANOTHER DOCTOR'S WIFE.

Glasgow, August 30th, 1912.

THE INTERNATIONAL DENTAL FEDERATION AT STOCKHOLM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—So far as I am aware, it does not seem that your excellent paper, or any of its medical contemporaries, are represented by correspondents at this Congress, and so I venture to send you some brief report of salient features, and some reflections upon them. The meetings are being held in the hall of the University, and the Federation is receiving the heartiest welcome and support from all the authorities, headed by the King and the Minister of Education. The King held a levée for the Federation, and singled out the President, Mr. W. B. Paterson, of London, in order to express his good wishes for the success of the work. In his address the President dwelt on the work accomplished by the Federation since its last visit to Stockholm in 1902, when the international dental hygiene movement was inaugurated, and on the high position attained by the

Federation as an advisory body, consulted by Governments on dental education and hygiene. Reports from other countries showed that gradually increasing interest was being taken in the question of oral hygiene and dental treatment as an integral part of public health. The care of the teeth of school children was one of the chief topics of discussion. In Germany there now exist 120 school dental clinics and 25 in Sweden. London has seven dental clinics, and some 20 others are established, or projected, in the provinces. In Denmark King Christian and in Holland the Queen Mother display personal interest in this matter. The United States Government has appointed 60 dental surgeons with commissioned rank to the Navy. The Sea Service is thus placed on the same footing as the land forces in respect of the *personnel* and status of dental officers.

The next Congress is to be held in London in August, 1914.

And now for my brief reflections. In the year 1858 the College of Surgeons, after thorough deliberation, having become convinced of the necessity for the institution of a special education for dentists, obtained through the new Medical Act powers for creation of a degree, to be styled the Licence in Dental Surgery. It was, however, not until 1878 that legislative sanction was given to dental reform. By the Dentists Act of that year dentistry received final recognition as a branch of the medical profession, was affiliated to that profession, and placed under the same direction and control. The prolonged inquiries which proved the need for this measure fully established the fact that ignorance in dentistry, as in every department of surgery, is closely allied to cruelty; and, that, although the uneducated dentist does not, like the surgical operator, deal with issues of life and death, he must, however honest and well-intentioned, constantly inflict pain and injury which might be avoided, and very often must, by improper treatment, aggravate the mischief which he seeks to relieve.

The penal clauses of the Dentists Act, like those of the Medical Acts, were designed to enable the public to distinguish between qualified and unqualified practitioners. In this they have entirely failed, and it would be farcical, if it were not so serious, to notice that the fraudulent quack dentist, although he may not with impunity actually style himself "dentist," may use the words "dental surgery" in his advertisements, and palm himself off upon the public without difficulty as a duly qualified man. The quack is able to take the bread out of the mouths of qualified men, and by degrading the status of dentistry he is arresting the entry into the profession of the class of men who, not content with the dental diploma, are willing to work for the highest qualifications that the Universities and Medical Colleges have to bestow. It will be a good thing when the whole story can be authoritatively made public, and I trust that the MEDICAL PRESS, in the endeavours it is continuously making to promote Parliamentary inquiry, will not omit to include the dentists' case. The appointment of the Committee on Patent Medicines was in no small degree due to the labours of your paper; it ought to be encouraging towards further efforts in like directions.

I am, Sir, yours truly,
AN OCCASIONAL CORRESPONDENT.

MEDICAL OFFICERS OF HEALTH AND SANATORIUM BENEFITS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is of the utmost importance that the national campaign against tuberculosis should be launched on right lines. To use the machinery of the office of the local Medical Officer of Health may be the easiest course, but it is not the best one. Agreed, consumption is an infectious disease, but it cannot therefore be dealt with in exactly the same way as other notifiable diseases; and the Medical Officer of Health—already overworked—is not of necessity an expert on diseases of the chest.

What is required is a whole-time tuberculosis officer, who is a recognised expert, to act as consultant in friendly co-operation with the local family practitioner in the combat with this scourge. That, clearly, is the proper line of attack, and not the relegation of the whole matter to a department, which—important ally though it be in improving the public health—is, in the matter of tuberculosis, in many instances out of touch with the actual treatment of patients.

Medical Officers of Health may be experts in diagnosing infectious diseases in the ordinary acceptance of that term; but the fact that tuberculosis has recently, and rightly, been included in the list by official decree does not endow this important service with a special training in diseases of the chest. They cannot become specialists in a moment. Efficiency in this matter can only be attained by separating the duties of the tuberculosis officers from those of the Medical Officers of Health.

I am, Sir, yours truly,

J. WEBSTER WATTS,

Secretary, National Medical Union.

National Medical Union,

Manchester, August 30th, 1912.

OBITUARY.

MR. CLINTON T. DENT.

WE deeply regret to announce the death of Mr. Clinton Thomas Dent, Senior Vice-President of the Royal College of Surgeons of England, which took place last week in a West End nursing home, at the age of 62. The deceased, who was the fourth surviving son of Thomas Dent, was educated at Eton and at Trinity College, Cambridge. He studied at St. George's Hospital, qualifying as M.R.C.S. in 1875, and becoming F.R.C.S. two years later. He was also an honorary M.C. of Cambridge University. Mr. Dent's work as a Consulting Surgeon was well known. At St. George's Hospital he was House Surgeon in 1876, and between 1877 and 1897 held the teaching appointments of demonstrator of anatomy, surgical registrar, joint lecturer in physiology, lecturer in practical surgery, and demonstrator of operative surgery, and, since 1897, had been joint lecturer on surgery. By holding the appointment of Assistant Surgeon from 1880 to 1895 he established a record for the longest period that any member of the assistant staff had held office at the hospital. He became Full Surgeon in 1895, and was appointed Treasurer of the medical school in 1900. He was also Chief Surgeon to the Metropolitan Police and Consulting Surgeon to the Bêlgrave Hospital for Children.

As an Alpine climber Mr. Dent had attained considerable eminence, and an account of his expeditions would fill volumes. His first ascents were fairly numerous when account is taken of the fact that he entered upon his Alpine career a few years too late for the period when, in the words of Mr. William Mathews, "new ascents were as plentiful as blackberries." But his achievements were such as even those who founded the Alpine Club might have been proud of. He made the first ascent of the Aiguille du Dru after 18 unsuccessful attempts. A worthy sequel to this fine piece of work was the first ascent of the Rothhorn from the Zermatt side, the first ascent of that great peak having been that of Messrs. Leslie Stephen and Grove from Zinal. To Mr. Dent is due the credit of a minor expedition for which visitors to Saas owe him hearty thanks—the ascent of the Portienhorn, a little peak of engaging character. Mr. Dent's work in the Caucasus was in some respects even more valuable than what he did in the Alps, for in the days he climbed there the Caucasus needed exploring as well as climbing. To him fell the sad task of searching for the bodies of Fox and Donkin, who were killed on Koshtantall in 1888.

He joined the Alpine Club in 1872, was elected to the Committee in 1874, was Secretary from 1878 to 1880, Vice-President in 1884, and President in 1887. He took a large part in editing the Mountaineering volume of the Badminton Library, and published a

charming volume entitled "Above the Snow Line" (Longmans) in 1885. His contributions to the *Alpine Journal* were numerous.

Mr. Dent was in South Africa in 1899 and 1900 as a Medical Correspondent and Surgeon, and as a result of his experiences he contributed several valuable surgical notes and papers on gunshot wounds, etc., to the medical press. He was a member of the Athenæum, Oxford and Cambridge, Arts, and Burlington Fine Arts Clubs. He will be sorely missed by his many friends at St. George's Hospital.

MR. W. H. BROWN, OF NORTH SHIELDS.

By the death of Mr. William Henry Brown, of Northumberland Square, North Shields, that town has been deprived of one of its most prominent medical practitioners and citizens. The deceased, who was 52 years of age, was a native of Whiteacre, near Beccles, where his father, the Rev. W. H. Brown, was rector of the parish. He was educated at Yarmouth and Beccles Grammar Schools, at the City of London School, and at King's College, Cambridge, where he took his B.A. degree. He became M.R.C.S. and L.S.A. in 1886. He settled in North Shields 23 years ago, and purchased the practice of the late Dr. Bates. Mr. Brown was a devoted Churchman, a licensed lay reader, and a member of the C.E.M.S. Volunteer work appealed to him, and he rose to the rank of Major in the Tyne Submarine Miners, and when that corps was reorganised he transferred to the Royal Army Medical Corps. As a Freemason he held the position of Worshipful Master of the Angus Mark Lodge of Wallsend, a Past Master of St. Oswin's Lodge, North Shields, P.Z. in the Ogle Royal Chapter, North Shields, P.P.G.H. in the Provincial Grand Chapter of Northumberland, and D.C. in the Provincial Grand Lodge of Northumberland.

MR. CHARLES EDE, OF BRAMLEY.

THE death occurred last week, at Bramley, near Guildford, of Mr. Charles Ede, who was a nonagenarian and a retired Staff Surgeon in the Navy. The deceased, who qualified as M.R.C.S. and L.S.A. in 1844, entered the Navy in 1845, serving on the Pacific station until 1849. He was then appointed Surgeon and Naturalist to H.M.S. *Assistance*, which took part in one of the numerous expeditions in search of Sir John Franklin, who, with Captain Crozier, had set out in May, 1845, for the Arctic region. The *Assistance* found the first trace of the missing expedition at Cape Riley—a boarding pike to which was attached a tin hand pointing in the direction of Beechey Island. Taking that direction, the search party found the first winter quarters of Franklin's party at the back of Beechey Island. There were three graves there, and a good deal of the *débris* of the expedition. At Griffith Island the search party were frozen in. Mr. Ede went with the first sledge party that set out exploring the coast line of Cornwallis Island, where other ships were found. He went westward with a search party to Cape Walker, from which point he had to return to his ship in charge of four frost-bitten men and two who were snow-blind. All the six men recovered.

Upon his return to England, in 1851, Mr. Ede settled down in Bramley, where for more than 55 years he practised as a surgeon.

DR. W. L. HEATH, OF LONDON.

WE regret to record the death of Dr. William Lenton Heath, M.D. F.R.C.S., which took place last week at South Kensington, where he had been actively engaged in medical practice for 30 years. The deceased, who studied at St. Bartholomew's Hospital, qualified in 1877, afterwards serving successively as House Physician, House Surgeon, Resident Midwifery Assistant, and Assistant Chloroformist to the hospital. Dr. Heath was a prominent member of many of the medical societies, and he was possessed of a charming personality and a fine presence. Among his contributions to the medical journals was the report of a case of dislocation of the shoulder in a patient 94 years of age. Dr. Heath was 58 years of age.

SPECIAL REPORTS.

INSANITY IN IRELAND.

THE annual report of the Inspector of Lunatics is now published, from which we gather that the total number of insane in Ireland on January 1st, 1912, was 12,868 males and 11,787 females, as compared with 12,704 and 11,690 respectively on the corresponding date of last year, showing a total reduction of 261, which, in view of the general increase elsewhere, is reassuring.

The local distribution of insanity being a matter of some interest and importance in connection with its causation, an attempt has been made to arrive at some information on this subject. The returns of the Census of 1911 being not yet fully available, the criterion fixed upon was the number of insane belonging to each county who were resident in public asylums (other than criminal) and workhouses about the beginning of the year under review. The number for the whole of Ireland was 23,174, or 5.3 per 1,000 of the present population; but the distribution is very unequal, varying from 2.6 per 1,000 in Co. Down to 9.2 in Waterford. No less than 21 counties are equal to or above the average, the eight highest being, in order, Waterford, Kilkenny, Westmeath, Monaghan, Clare, Carlow, Meath and Tipperary, while the eight lowest are Down, Derry, Kerry, Fermanagh, Tyrone, Mayo, Antrim and Donegal.

The very large proportion of insane in Co. Waterford is exceedingly difficult to explain, but, upon the whole, it appears that insanity tends to prevail in the agricultural and rural counties, to which category belong the eight which head the list; while, on the other hand, Antrim, containing the greater part of Belfast, is well below the average with 4.7 per 1,000; Down, with the remainder of Belfast, is lowest of all; and Armagh, Tyrone and Derry, with their smaller manufacturing towns, stand near the bottom. As against this, however, Dublin comes about the middle of the list, and Cork and Limerick are high; but the two latter have large agricultural areas to neutralise the effect of the cities, while as regards Dublin, the same tendency which draws vagrants to the capital probably operates to some extent in the case of the insane. The order of the four provinces is—Munster, 6.1 per 1,000; Leinster, 6.0; Connaught, 5.2; and Ulster, 4.2.

It is found that no appreciable connection exists between the distribution of insanity and the density of population, but a considerable degree of correspondence exists in the distribution of poverty and that of insanity. Thus Waterford, with the second highest rate of insane in institutions, has also the second highest rate of pauperism, and all but two of the counties which stand over the average in pauperism were also over the average in insanity. In comparing the emigration and insanity rates, it is found that no marked degree of relationship exists.

Referring to alcohol as a cause of insanity, the report says that the personal equation here comes so much into play that too much importance should not be attached to the figures. With the probabilities in favour of an over-estimate rather than an under-estimate, it is satisfactory to find that the average for the five years 1905-9 for the whole country was only 10.3 per cent. The general conclusion that may be safely drawn from the facts is that alcohol possesses comparatively small importance as a cause of insanity in Ireland.

REVIEWS OF BOOKS.

PREVENTABLE CANCER. (a)

THE author holds well-known views that cancer to a large extent may be a disease due to over-feeding, toxic beverages and worry.

More especially, in his opinion, the large consumption of beer, tea, coffee, alcohol, etc., has contributed to the high rate of cancer prevailing in various coun-

(a) "Preventable Cancer." By the Hon. Rollo Russell. Pp. 463. Longmans, Green and Co. 1912. Price 4s. 6d. net.

tries, while countries not using such in excess had little or no cancer.

In the present volume such views are elaborated and supported by a wider investigation; the various food and drink factors are regarded as chronic internal irritants, analogous to irritants which are known to be associated with certain forms of external or skin cancer; while the use of hot foods and drinks far above the body temperature may act in the same way as certain external forms of heat, and thus in part explain the occurrence of cancer in persons who live most temperately.

Similar views have long been entertained by medical observers, and the association of certain forms of superficial cancer with chronic irritation recognised. On the other hand, it is generally held that none of the conditions are the essential, direct or constant cause of the disease, however much they may be subsidiary. The author contends that it is impossible to separate such admitted subsidiary conditions from an essential or direct cause; and "if certain occupations, if certain habits of drinking, if certain diets entail a great excess of cancer, and if certain other bland or plain diets, and avoidance of irritants confer a great freedom from liability, then for practical purposes, to multitudes of people, to the world in general, it does not much matter whether the cause is direct or indirect." The facts, however, that similar conditions produce disease other than cancer, that every individual exposed to the same conditions does not inevitably develop cancer, seem to us to show that such conditions are not essential and that some other primary cause exists. The author's own simile, adduced in favour of combined causes seems to favour a specific cause. He tells us that the position of the question of cancer-causation resembles in one respect that of malaria-causation a few years ago. "All the elements for the discovery of the cause were there. The effect of drainage, season, height above the ground, neighbourhood of pools, and of mosquito nets had been observed. . . . The discovery of the malaria microbe in the mosquito . . . led to a proof of the ætiology beyond question." In the same way there are authorities who favour a parasitic origin of cancer—some causal germ which, though not yet isolated, may be a continuous stimulus to cell growth; others hold to an embryonic origin; or reversion to embryonic type of "soil," with intrinsic power of the cell to multiply—events connected essentially with the "life-cycle."

In neither of such hypotheses are chronic irritation or nutritional factors denied; on the contrary, such influences are admitted.

While not ignoring pathological or clinical considerations, the author bases his conclusions in favour of inappropriate food, drink, and other sources of irritation in the causation of cancer, chiefly, on a large number of statistics collected from various countries and sources. With the qualifications necessary to be borne in mind, as the author states (differences of enumeration, classification, diagnosis, in different countries, age incidence, etc.), the tables are striking. We have read this book with much interest, and recommend it to others as an able and conscientious contribution to a complex and all important subject.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

ADLARD AND SON (London).

Deuxième Congrès de L'Association Internationale D'Urologie. Edited by J. G. Pardoe, F.R.C.S. Pp. 673. Price, 10s. net.

ARNOLD, EDWARD. (London).

Internal Secretion and the Ductless Glands. By Swale Vincent, M.D. Lond., D.Sc. Edin., etc., etc., with preface by Prof. E. A. Schäfer, F.R.S. Illustrated. Pp. 664. Price 12s. 6d. net.

The Treatment of Diseases of the Skin. By W. Knowsley Sibley, M.A., M.D., etc., etc., etc. Pp. 280. Price 5s. net.

BAILLIÈRE, TINDALL, AND COX (London)

Medical Laboratory Methods and Tests. By Herbert French,

M.A., M.D.Oxon., F.R.C.P.Lond. Third Edition. Illustrated. Pp. 202. Price 5s. net.

Aids to Tropical Hygiene. By Major R. J. Blackham, D.P.H.Lond., R.A.M.C. Pp. 192. Price, cloth, 3s. net; paper, 2s. 6d. net.

Prescribers' Formulary and Index of Pharmacy. By Thomas Pugh Beddoes, M.B., B.C.Camb., F.R.C.S.Eng. Pp. 132. Price 2s. 6d. net.

Medico-Legal Examinations and the Workmen's Compensation Act, 1906. By Sir John Collie, M.D., J.P. Pp. 128. Price 6s. net.

The Treatment of Infantile Paralysis. By Oscar Vulpius, M.D. Translated by Allen H. Todd, M.B., B.S., B.Sc.Lond., with introduction by J. Jackson Clarke, M.B.Lond., F.R.C.S. Illustrated. Pp. 318. Price 10s. 6d. net.

The Clinical Pathology of Syphilis and Parasyphilis and Its Value for Diagnosis and Controlling Treatment. By H. W. Bayly, M.A., M.R.C.S., L.R.C.P. Illustrated. Pp. 194. Price 5s. net.

BLACK, ADAM AND CHARLES, London.

Black's Modern Guide to Harrogate. Edited by Gordon Home. Illustrated. Pp. 128. Price 1s.

CHURCHILL, J. AND A. (London).

A Clinical Manual of the Malformations and Congenital Diseases of the Fœtus. By Prof. D. R. Birmbaum. Translated and Annotated by G. Blaoker, M.D., B.S., etc., etc. Illustrated. Pp. 379. Price 15s. net.

The Treatment of Ringworm. By J. E. Sequeira, M.D., F.R.C.P., F.R.C.S. Pp. 11. Price 1s. net.

Royal London Ophthalmic Hospital Reports. Edited by William Lang, F.R.C.S.Eng. Vol. 18, Part 3; July, 1912. Price 5s. net.

CHUNDRRA, Dr. J. L. (Calcutta).

A Treatise on Treatment. By J. L. Chundrra, L.M.S. Illustrated. Pp. 684. Price Rs.9.6.

CORNISH BROS. (Birmingham).

Insomnia: Its Causes and Treatment. by Sir James Sawyer. Second Edition, with many revisions and additions. Pp. 107. Price

DUNLOP PRINTING Co. (Philadelphia).

Philadelphia General Hospital Reports. Vol. 8, 1910. Edited by David Riesman, M.D. Pp. 375.

FERRIS AND Co. (Chicago).

Herself: Talks with Women Concerning Themselves. By E. B. Lowry, M.D. Pp. 221. Price 1 dol. net.

Truths: Talks with a Boy Concerning Himself. By E. B. Lowry. Pp. 95. Price 50 cents net.

Confidences: Talks with a Young Girl Concerning Herself. By Dr. E. B. Lowry. Pp. 94. Price 50 cents net.

False Modesty That Protects Vice by Ignorance. By Dr. E. B. Lowry. Pp. 110. Price 50 cents net.

FROWDE, HENRY, AND HODDER AND STOUGHTON (London).

Consumption in General Practice. By H. Hyslop Thomson, M.D., D.P.H. Pp. 235. Price 12s. 6d. net.

X-ray Diagnosis and Treatment. By W. J. S. Bythell, B.A.Cantab., M.D.Vict., and A. E. Barclay, M.D.Cantab., M.R.C.S., L.R.C.P. Pp. 147. Price 15s. net.

Pathology of the Eye. By P. H. Adams, M.A., M.B., etc., etc. Pp. 194. Price 5s. net.

LEWIS, H. K. (London).

The Extra Pharmacopœia of Martindale and Westcott. Revised by W. Harrison Martindale, Ph.D., F.C.S., and W. Wynn Westcott, M.B.Lond., D.Ph. Fifteenth Edition. Vol. 1. Pp. 1,114. Price 14s. net. Vol. 2. Pp. 370. Price 7s. net.

Elements of Practical Medicine. By Alfred H Carter, M.D., M.Sc. Tenth Edition. Pp. 683. Price 9s. net.

LIVINGSTONE, E. AND S. (Edinburgh).

Public Health Law. By William Robertson, M.D.Glas., D.P.H., and Archibald McKendrick, F.R.C.S.Edin., D.P.H. Pp. 397. Price 6s. net.

LONGMANS, GREEN AND Co. (London).

Proceedings of the Royal Society of Medicine. Commemoration Number. Vol. 5. No. 8. June, 1912. Price 7s. 6d. net.

MACMILLAN AND Co., LTD. (London).

A Text Book of Pathology for Students of Medicine. By George Adams, M.A., M.D., F.R.S., and John McCrac, M.D., M.R.C.P.Lond. Illustrated. Pp. 759. Price 25s. net.

SAUNDERS, W. B., COMPANY (Philadelphia).

Collected Papers of the Staff of St. Mary's Hospital. Mayo Clinic, 1911. Illustrated. Pp. 603. Price 24s. net.

The Surgical Clinics of Dr. John B. Murphy. Vol. 1. Part 3. Illustrated. Pp. 170. Price per year of six numbers (one every other month) 35s. net.

Sexual Impotence. By Victor G. Veckl, M.D. Fourth Edition. Enlarged. Pp. 394. Price 10s. 6d. net.

Infant Feeding. By Clifford G. Grulee, A.M., M.D. Illustrated. Pp. 295. Price 13s. net.

Surgical After-Treatment. By L. R. G. Crandon, A.M., M.D., and Albert Ehrenfried, A.B., M.D. Second Edition. Revised and Illustrated. Pp. 831. Price 23s. net.

SELL, C. H. (London).

Low's Handbook to the Charities of London, 1912. Pp. 250. Price 1s.

SHAW AND SONS (London).

Symptoms and Their Interpretation. By James Mackenzie, M.D., LL.D. Second Edition. Pp. 304. Price 7s. 6d. net.

SOCIETE D'EDITIONS SCIENTIFIQUES ET MEDICALES (Paris).

Les Produits Biologiques Médicinaux. By C. Bylu et R. Delauney. Pp. 466.

STANLEY PAUL AND Co. (London).

The First Signs of Insanity: Their Prevention and Treatment. By Bernard Hollander, M.D. Pp. 547. Price 10s. 6d. net.

STEINKOPFF, THEODOR (Dresden).

Leitfaden Der Praktischen Kreis-Chirurgie von Dr. Walter von Vettingen. Pp. 377.

TAYLOR AND FRANCIS (London).

Fifth Scientific Report on the Investigations of the Imperial Cancer Research Fund. By Dr. E. F. Bashford. Pp. 94. Price 5s. net.

WILEY AND SONS, J. (New York). CHAPMAN AND HALL (London).

Enzymes. By Prof Otto Cohnheim. First edition. Pp. 173. Price 6s. 6d. net.

A Laboratory Manual of Inorganic Chemistry. By J. B. Ekeley, Ph.D., Sc.D.; to accompany a text-book of Inorganic Chemistry by C. F. Holleman, Ph.D., F.R.A.Aust. First Edition. Pp. 128. Price 4s. 6d. net.

Manual for Women's Voluntary Aid Detachments. By P. C. Gabbett, M.R.C.S., Lieut-Col. Retired. Pp. 103. Price 1s. net.

Small-Pox and Its Diffusion. By Alexander Collic, M.D., Aberdeen. Pp. 55. Price 2s. net.

WRIGHT, JOHN, AND SONS, LTD. (Bristol).

Statistics of Puerperal Fever and Allied Infectious Diseases. By George Geddes, M.D., C.M.(Aber.). Pp. 119. Price 6s. net.

MEDICAL NEWS IN BRIEF.

The International Federation of Pottery Workers.

THE third triennial Congress of the International Federation of Ceramic Workers was held at Hanley last week. The main objects of the Federation have been the consideration of problems affecting the workers in the ceramic industry, such as hours of labour, occupational disease and its remedies, and the general questions of labour organisation and disputes. The national reports presented to the Congress were chiefly interesting for their references to the ravages of tuberculosis in the potting industry in Germany. It was stated that 50 per cent. of the deaths of pottery operatives were from diseases of the respiratory organs. No special regulations were in force to protect the workpeople. Austria and France reported that nothing was done by legislative bodies to limit the terrible effects of tuberculosis. In France even the existing regulations were not applied. Employers were openly violating them every day, and all protests directed to the public authorities were disregarded.

A Tuberculosis Scheme for Essex.

At a meeting of the Essex County Council, held in London last week, it was decided to appoint three tuberculosis officers for the county, and to spend £4,000 in the provision of dispensaries.

It was also decided to negotiate with the King Edward County Memorial Committee for the taking over of the open-air shelters which they had obtained. It was stated that this was a temporary scheme for immediate operation, and a larger and more comprehensive scheme would be submitted later.

Death of a Surgeon-General.

THE death occurred at Cheltenham last week of Surgeon-General Duncan Alexander Campbell Fraser, at the age of 80. He was a son of the late Rev. Hugh Fraser, minister of Ardochattan, Argyllshire. After graduating at Edinburgh he served for nearly 40 years in the Army Medical Service, among his Staff appointments being the medical commands at Netley and Malta. He held the medal for the Ashanti War 1873-4 and the Star of Roumania for services as a Commissioner of the Red Cross Society in the Russo-Turkish War.

Memorial to a Medical Man.

A MEMORIAL in the shape of a handsome tablet of Sicilian marble with gilt mosaic border has recently been placed in the main corridor of the Royal Portsmouth Hospital to commemorate the life and work of the late Dr. C. C. Claremont, formerly a member of the Staff, who died on April 11th, 1911.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8 Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Dr. T. I. Y.—A high deviation of the nasal septum may cause pain over the bridge of the nose by pressure upon the anterior ethmoidal nerve.

E. S. (Thurloe).—In reply to your inquiry, the only reference we have been able to trace is in a paper by Mr. Arbuthnot Lane in the *British Medical Journal* of May 4th of the present year.

WORKMEN'S COMPENSATION ACT, 1906.

We are asked to insert the following official notice:—"The Home Secretary gives notice that in consequence of the resignation of Dr. P. J. Hay, the appointment of Ophthalmic Specialist Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 16 is now vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than the 25th September."

MR. P. COOK (Harrow).—Phenolphthalein, the well-known indicator used in volumetric analysis, is largely used as a prompt and safe purgative. It is prepared by the interaction of phenol and phthalic anhydride. The dose is from one-half to ten grains.

DR. A. L. (Hants).—The subject, we understand, is to be dealt with by several speakers at the forthcoming annual meeting of the American Hospital Association, to be held at Detroit, Michigan, from September 24 to 27.

A NEW SANITARY DUST COLLECTOR.

ONE of the prominent features of the special anti-tuberculosis exhibition organised by the Society of Medical Officers of Health at 1 Upper Montague Street, Russell Square, is an improved form of dust and refuse collector after the plan adopted at Zurich, and the system exhibited is so designed as to prevent the rubbish being even exposed to the outside air. Each household has a special tin for the collection of his household rubbish. This is so contrived that it fits into a groove on the cart, and on being slid from the side to the centre pushes aside a trap door in the cart and at the same time automatically removes the bottom of the tin. On sliding the tin back the opening in the cart is again brought into position, and the bottom side of the rubbish tin replaced. The cart is contrived so as to open from below and to deliver its contents either into a rubbish shoot or a destructor.

DR. BRISBY.—Nothing that we know of would militate against the adoption of the suggested proposal.

PARSON'S GREEN.—In healthy persons antityphoid vaccination is quite harmless.

Appointments.

APAMS, A. M.B., B.Ch., M.D., D.P.H., Resident Medical Officer of the Liverpool Sanatorium, Kingswood.

BLEASE, A. T., M.B., Ch.B., District Medical Officer of the Bucklow Union.

CLARKE, T. C., M.B., Resident Assistant Medical Officer of the Crumpsall Workhouse, Manchester.

JEFFREY, JOHN, M.B., B.S. Edin., F.R.C.S., Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Berwick, Roxburgh and Selkirk, to be attached more particularly to the County of Roxburgh.

SMITH, J. LORRAIN, M.D. Edin., to the Chair of Pathology in the University of Edinburgh.

TAYLOR, J. M., M.B., Ch.B. Glasg., District Medical Officer of the Thorne Union.

WEST, H. O., M.B., B.S. Lond., Tuberculosis Officer for the County of Kent.

Vacancies.

Beckett Hospital and Dispensary, Barnsley.—Second House Surgeon. Salary £100, with apartments, board and laundry provided. Applications to R. F. Pawsey, Honorary Secretary, 8 Regent Street, Barnsley.

Coton Hill Lunatic Hospital, Stafford.—Assistant Medical Officer. Salary £150 per annum, with residence, board and laundry. Applications to the Medical Superintendent.

The Guest Hospital, Dudley.—Senior Resident Medical Officer. Salary £105 per annum, with board, residence, attendance and washing. Applications to the Secretary.

Asylum for the County Borough of Cardiff (Cardiff City Mental Hospital, Whitechurch), Cardiff.—Second Assistant Medical Officer. Salary £180 per annum, all found. Applications to the Medical Superintendent.

Lewes Victoria Hospital and Dispensary.—Resident Medical Officer. Salary £120 per annum, furnished apartments, board, coal, gas, washing and attendance. Applications to the Hon. Secretary.

Parish of Leicester.—Poor-law Infirmary.—Second Resident Assistant Medical Officer. Salary £150 per annum, with rations, furnished apartments and washing. Applications to Herbert Mansfield, Clerk to the Guardians, Poor-law Offices.

Herts County Asylum, Hill End, St. Albans.—Junior Assistant Medical Officer. Salary £160 a year, with board, lodging and washing. Applications to the Medical Superintendent.

Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £100 per annum, with residence, board and washing. Applications to John Potter, Secretary.

North Devon Infirmary, Barnstaple.—House Surgeon. Salary £100 per annum, with board, residence and washing. Applications to Chairman, House Committee.

Hants County Asylum.—Third Assistant Medical Officer. Salary £168 per annum, with furnished apartments, board, washing and attendance. Applications to the Visiting Committee, Hants County Asylum, Fareham.

Leicester Royal Infirmary.—House Physician. Salary £100 per annum, with board, lodging and washing. Applications to Harry Johnson, House Governor and Secretary, Board Room.

County and City Asylum, Powick, Worcester.—Junior Assistant Medical Officer. Salary £160 per annum, with board, furnished apartments, washing and attendance. Applications to Medical Superintendent.

Brecon and Radnor Asylum, Talgarth, Breconshire.—Assistant Medical Officer. Salary £170 per annum, with board, furnished apartments, washing and attendance. Applications to the Medical Superintendent.

Births.

CARDEW.—On August 26th, at Shire Lane, Chorleywood, Herts, to Violet, wife of Henry J. Cardew, M.A., M.B. Camb.—a son.

UNWIN.—On July 17th, at Timaru, New Zealand, to Dr. W. H. and Mrs. Unwin—a son.

Marriages.

BRIDGER—AYLWIN-FOSTER.—On August 27th, at St. Andrew's Church, Biggleswade, Robert Daniel Bridger, M.R.C.S., L.R.C.P., third son of the late Robert Bridger, of Monteideo, to Dorothy Noel Aylwin, second daughter of the late Rev. Edmund Clement Aylwin-Foster, Rector of Clifton, Beds.

BURNEY—ROLLESTON.—On August 20th, at Nun's Cross Church, Captain Walter Henry Skardon Burney, R.A.M.C., son of Walter Burney, Esq., M.D., of Blackheath, to Phoebe Elizabeth, youngest daughter of the late Henry Rolleston, of Glasshouse, King's County.

HART—SPARK.—On August 28th, at St. Clement Danes, Strand, Bernard Hart, M.D., to Mabel Emily, youngest daughter of the late Charles E. Spark and of Mrs. Spark, of Ealing.

RIGDEN—GRAY.—On August 28th, at St. Jude's, South Kensington, Dr. Walter Rigden, of Thurloe Place, to Mrs. John Trev Gray, of 28, Bramham Gardens.

WILSON—HOLFORD.—On August 27th, at St. Clement Danes Church, London, Archibald Wilson, M.D., of Toronto, Canada, to Naomi Eleanor, youngest daughter of Josiah Holford, of Little Comberton, Worcestershire.

Deaths.

BIDWELL.—On September 2nd, at 15 Upper Wimpole Street, W., after an operation for appendicitis, Leonard Arthur Bidwell, F.R.C.S., Senior Surgeon to the West London Hospital, aged 47.

FRASER.—On August 25th, at 13 Lypiatt Terrace, Cheltenham, Surgeon-General D. A. Campbell Fraser.

GARLICK.—On September 2nd, at Worthing, George Garlick, M.D. Lond., of Gordon Square, Bloomsbury, as the result of an accident.

HEATH.—On August 25th, at St. Ann's Heath, William Lenton Heath, M.D., late of 90 Cromwell Road, South Kensington, aged 53.

WICKHAM.—On August 29th, Charles Thomas Wickham, M.R.C.S., L.S.A., of Sutton Scotney, Hants., late of Winchester, aged 89 years.

THE MEDICAL PRESS AND CIRCULAR

"SALUS POPULI SUPREMA LEX."

VOL. CXLV.

WEDNESDAY, SEPTEMBER 11, 1912.

No. 11.

NOTES AND COMMENTS.

The Origin of Life.

THE Presidential address of the year 1912 seems likely to leave its mark in the annals of the British Association. It was delivered by Professor Schäfer, a distinguished physiologist and member of the medical profession, who turned for his text to that ancient and ever-fascinating problem of the human mind—the origin of life. It cannot be said that he has contributed any fresh facts, or advanced any new theory upon the subject. On the other hand, he has done good service to the world at large by drawing attention to the limitations of our scientific knowledge as regards the jumping-off point—so to speak—of living matter upon the earth. He has also expressed in the terms of clear and lucid statement the latter-day position as regards the relations of the element to the protoplasm that constitutes the formal basis of life. The student commencing the study of biology will do well to follow carefully the words of a master in his discussion of one of the profound mysteries of creation; a task to which he brings the manifold resources of a scholarly, bold, and yet reverent mind. His main propositions are simple. The elements comprising living matter, as we all know, are few in number. Those constantly present are carbon, hydrogen, oxygen, nitrogen and phosphorus; and all active living matter is associated, on an average, with 70 per cent. of water. Certain inorganic salts are also essential to life, such as chloride of sodium, and the salts of calcium, magnesium, potassium, sodium, and iron. All these substances are bound up into a sort of colloidal jelly. In this new form they are enabled to react upon their environment and display that mysterious and evasive quality which we distinguish by the term "life."

The Formal Basis of Life.

THEN comes the second proposition, namely, that the modern chemist has the elements at command in his laboratory, and, step by step, by the aid of synthetical chemistry, is surmounting the frail barrier still left between him and the actual making of protoplasm, as it were, in his test-tube. When he has succeeded in manufacturing the "colloidal jelly" we shall have, at any rate, the elementary machinery of life, but it will still remain to be seen whether this man-made structure will responsively spring into motion. In other words, whether life is merely the expression of chemical reactions between certain definitely compounded substances and the various stimuli of the outside world. That is broadly what Professor Schäfer appears to regard as life. On the other hand, Sir Oliver Lodge defines the visible or tangible reaction itself as "vitality," and that essential quality or power—call it what you will—

which connects the two as life itself. In any case, the view that some day or other the material basis of life would be produced by chemical means has been pre-shadowed in the writings of Huxley, Ray Lancaster, Sir Oliver Lodge, and many others.

The Gem of the Address.

FOR all that, Professor Schäfer had much to say that was novel and stimulating with regard to life. At the outset he set aside, as devoid of scientific foundation, the idea of direct supernatural intervention in the creation of life from the original colloidal watery slime, or the ultra-microscopical particles which previously constituted the transitional material between dead and living matter. Obviously it is impossible to obtain evidence of any such frail evolutions from a study of the geological history of the globe. Then came the gem of this philosophical discourse. If in the past living matter has been evolved from that which was lifeless we are justified in holding that a similar evolution is possible, both in the present and in the future. Therein lies the stimulus for research, and it may well set in motion the minds of scientific workers throughout the world. Let the student reflect that the solution of this problem, which has vexed the mind of man ever since his brain cells became capable of dealing with abstract ideas, happily lies at his own elbow in the simplest and least complicated of biological beginnings. Had Dr. Schäfer advanced no other proposition, that alone would have stamped his address with distinction.

Death.

WHAT should be the source of that human life which recapitulates the experiences of untold ages of evolution? The answer is that, normally, man should die of old age, by a painless cessation of the sum-total of the activities that have been crystallised into his span of life. That man should die of old age, and of that alone, is, and always has been, the practical working assumption of medical science. Apart from accidents, which must happen in the human as in all other families, each of us individually should be entitled, in any well-governed community, to look forward to a hale and ripe old age well over a century of years, followed by gradual and well nigh imperceptible extinction. Not many years ago a stout old Bristol centenarian was cleaning his own windows and walking five to ten miles a day. Medical science, by teaching the rules of health and securing a good environment, does its best to bring a like possibility within the reach of all of us. Many distinguished men have attempted to find the secret of long life. Metchnikoff, arguing from the longevity of certain hill-dwelling

natives, who consumed much sour milk, devised the lactic acid theory with a *lacto-bacillus* as the *elixir vite*, but he himself has since abandoned this view, so we gather, in favour of a bacillus inhabiting the lower intestine of the dog. Unfortunately, the dog itself is a short-lived animal, but that fact does not necessarily mean that it may not act as host to Metchnikoff's long-sought micro-organism.

The Dawn of the Health Age.

CLEARLY the labours of medicine have always been intended to shield mankind from the multitudinous diseases with which Nature has seen fit to encompass his path. The crudest efforts of the savage medicine man are simply blind gropings in this direction. Even nowadays, when medicine is making rapid strides towards the secure foothold of an exact science, much of the work of actual practice is based on purely empirical grounds, and the best men in the profession are forced to trust to a balance of probabilities where as yet there is no chart to justify his pilotage. Happily the region of the unknown is being rapidly reduced day by day. Within the experience of the present generation the cause and the cure of syphilis have been surrendered into our hands; the marvellous achievements of modern surgery, rendered possible by the genius of Lister, have been multiplied in all directions; the causation of yellow fever, sleeping sickness, Malta fever, malaria, influenza, and many other diseases, has been identified; preventive and curative serum-therapy has been laid upon a secure foundation; the life-expectation of the individual citizen has been materially raised; and in many other ways medical science has been winning all along the line. There is much to be done, however, before civilised existence is brought to such perfection that the average man may expect to live to a hundred years or more. Meanwhile, one thing is particularly clear, namely, that the mortality is greater among the industrial than among the better-to-do classes. That fact has furnished the text for a vigorous onslaught by Professor B. Moore on existing systems of medical treatment in a book entitled "The Dawn of the Health Age."

Contract and Voluntary Practice.

ANYONE acquainted with the conditions of modern Poor-law and voluntary hospital practice must agree with much that is said by Professor Moore. In Poor-law infirmaries the medical and nursing staff are often inadequate, there is a lack of skilled surgery, and there are other obvious administrative and statutory shortcomings. Poor-law outdoor relief is for the most part inadequate, perfunctory and worthless. Something of the same kind may be said with regard to out-patient treatment in the voluntary hospitals. It is physically impossible for justice to be done to the crowds of patients, either in the way of diagnosis or of treatment. Club practice is in a still worse condition. The friendly societies have driven a hard bargain with the doctors, whose remuneration has been cut down to a bare subsistence level, in spite of a grievous amount of over-work thrust upon the medical officers. The result is hurried, superficial and unsatisfactory medical attendance. One main argument advanced by Dr. Moore is that under present systems the sick man is not adequately treated at the beginning of his illness, a neglect that later saddles the nation with a vast burden of crippled and unproductive workers. His remedy is a public medical service under the control of our own profession. There is much to be said in favour of the scheme, which, indeed,

may prove within the next few months the only rock of refuge in our refusal to work the National Insurance Act upon the terms set forth in the Statute Book.

The Insurance Act.

THERE can be little doubt that in the long run the National Insurance Act will yield yeoman's service in the cause of health. Not only will men, women and children be tended in the early days of sickness, but the family will be assured of subsistence money when working members are thrown out of employment. From the standpoint of health, it is of value to maintain a fairly good standard of nutrition in the healthy as well as to treat or attempt to patch up the sick—especially when that attempt is made by the makeshift and that piecemeal organisation, the regulation of which has been pulverised by Dr. Moore. Then the Act furnishes for the first time a comprehensive national scheme for dealing with consumption. Lastly, it provides substantial help for the mothers of the nation. In all these ways the Act may be welcomed as a fit herald of the dawn of the health age. Had the Government arranged terms with the medical profession before instead of after the passage of the Act, there would probably have been no hitch in the administration of medical benefits. Mr. Lloyd George, however, appears to have leant on a broken reed in the shape of the advice of certain medical politicians of the Council of the British Medical Association. The latter executive body has been pretty sharply rapped over the knuckles, and can now fairly claim to be representative of the profession generally. Whatever views the medical man may hold individually, we hold it to be his bounden duty to support the Association policy in the present crisis. Students may be advised at the outset of their career to consider well the necessity of subordinating self to the common interest of a noble, but so far somewhat unbusinesslike and opinionated, profession.

A Medical Man's Hobbies.

THOUGH it can never be said of medicine that its practice is monotonous, for few callings present so many opportunities for work of ever-changing interest, yet there is an imperative need for every practitioner to get out of the daily professional groove and to vary the currents of his thoughts. Now and then it has happened that these "lesser things of life" have gradually monopolised the whole of a man's activities to the ultimate exclusion and forsaking of his original life-work. This, of course, is rare, and when instances come to our notice of medical men leaving their profession to take up some other occupation it is but natural to conclude that many of these are really cases of mistaken vocation. An ideal hobby should consist of some occupation absolutely unconnected with the routine duties of life, for anything beyond this becomes simply an additional vocation. Whether it be some form of outdoor recreation or sport, such as fishing, golf, or motoring, or an indoor pursuit, such as literature or one of the fine arts, he who so indulges should remember he is out for amusement and relaxation rather than for hard work. The reproach is sometimes cast at medical men, and especially at medical students, that they either talk "shop" or sport. This is true, to a great extent, and, unless carried to excess, is nothing to be ashamed of, but a greater widening of a medical man's sympathies in as many directions as possible is much to be desired in the interests of their patients.

Other Accomplishments. THE value of an intimate knowledge of one or more foreign languages soon becomes apparent to the medical student. Not only will he be at a great disadvantage when interviewing foreign patients if he cannot converse with them in their own tongue, but he will speedily find out that he is debarred from learning at first-hand the latest medical achievements recorded in the various Continental journals. It is much better to be able to go straight to the source of information rather than depend upon translated abstracts, some of which may be considerably belated. A working knowledge of French or German, preferably both, is of great assistance to all who desire to be *au courant* with the latest medical and scientific work of the day. Another useful accomplishment for the medical man is a knowledge of shorthand. He may have to take down a dying deposition, where it is important that a *verbatim* report should be made, or he may wish to take the fullest possible notes of some medical lecture or address. Medical phonography is an art well worth learning and cultivating, for it is likely to be useful in all sorts of circumstances and emergencies, as, for instance, when giving medical evidence in the witness box, when original notes may be consulted.

Nurses and Natives. FROM time to time agitation springs up in one or other of the Colonies to put an end to the nursing of natives by white women. Quite recently in the Cape Provincial Council an amendment to the Hospital Ordinances was proposed, which would have put a stop to the practice of employing white nurses in native wards. It is curious that all agitations of this kind arise outside hospital circles, and that neither of the classes—medical men and nurses—best qualified to have an opinion on the matter, have joined therein. The truth is that the abuses which are alleged to be so likely to arise, do not exist. As a matter of fact, it is found in mixed hospitals that, as a rule, nurses prefer the coloured to the white wards. They find that it is easier to maintain discipline among natives, and that the latter are more tractable and less exacting. There is, let us add, a positive objection, from the ethical point of view to depriving our coloured fellow-subjects of the help of white nurses in their illness. To forbid the nursing of natives by white women would be to hand them over to some inferior body of attendants. It is our duty, as a profession, in our care of our patient to give him the best attendance in our power, to cure him, if we can, *cito, tuto et jucunde*. In the absence of any grave reason for such action, and those qualified to judge declare that there is no such reason, we are not justified in substituting an inferior for the present system in our colonial hospitals.

The Motor Car Danger. IN our last issue we discussed the nuisance and danger of motor car traffic in town and country. It was pointed out that the key to nine-tenths of the nuisance was to be found in excessive speed, especially in the case of the heavy motor omnibus, which is by far the worst offender in our towns. Cut down speed to a reasonable limit and at one stroke the risks to life and limb of wayfarers, the intolerable noise and dust, the rumbling earthquakes that disturb our peace and dilapidate our dwellings would be reduced to vanishing point. In other words, the risks and the annoyance due to automobile traction are for the most part preventable, and as a commonsense

Anglo-Saxon community we must look first to local authorities and police to prevent them, failing which happy result we must turn to Parliament for relief. The police have shown a commendable wish to cope with the evil in London. Their action has apparently been due to the terrible toll in life and limb exacted from Londoners by the owners and drivers of motor vehicles. They have issued a caution that in future any chauffeur involved in an accident runs a risk of losing his licence. We commend to the Commissioners of the Metropolitan Police and to provincial chief constables the desirability of keeping, year by year, a map studded with pins, the heads of which denote by one colour fatal and by another non-fatal accidents. That would indicate infallibly the danger-points, and would enable the police to bring their observation to a focus. In all traffic there must be an unavoidable margin of fatalities, but nothing can justify the running down of a wayfarer by the driver of an automatically-driven machine anxious to cover the ground at an unreasonable rate of speed.

PERSONAL.

H.M. THE KING has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Dr. Robert Gordon McKerron, M.A., M.D., to be Professor of Midwifery in the University of Aberdeen in the place of Professor Wm. Stephenson, who has resigned.

DR. R. G. WADDY has been appointed Inspector of Ophthalmic Hospitals in the Egyptian Medical Service.

DR. H. HYSLOP THOMSON, M.D.Glasg., has been appointed Medical Officer under the King Edward VII. Welsh National Memorial Scheme.

MISS JANE WALKER, M.D., will deliver the introductory address at the London School of Medicine for Women on October 1st, on "Common Sense."

DR. H. D. ROLLESTON will deliver the introductory address at the University of Manchester on October 1st, on "Universities and Medical Education."

MR. GEORGE B. PEMBERTON, F.R.C.S.Edin., M.B., Ch.B.Edin., has been appointed Medical Officer of Health of the district of Disley, Cheshire, with Hayfield.

DR. HENRY PRIESTLEY, of the Lister Institute of Preventive Medicine, has been appointed Second Assistant at the newly formed Australian Institute of Tropical Medicine.

DR. R. W. A. SALMOND, M.D., Ch.M., D.P.H., has been appointed Medical Officer in Charge of the Electrical Department at the Queen's Hospital for Children, Bethnal Green, E.

DR. DOSSAIBI R. PATELL, the first Indian lady to obtain the M.D.Lond. and the diploma of the Conjoint Board, was entertained at dinner the other day at the Holborn Restaurant by Parsee residents in London.

IN consequence of the death of the Vice-Chancellor of the Birmingham University (Ald. C. G. Beale, M.A.) it has been decided, as a mark of respect, to abandon the usual October Conversazione to inaugurate the opening of the Medical Winter Session.

EDUCATIONAL SUMMARY FOR 1912-13.

INTRODUCTORY REMARKS.

THE following remarks are addressed mainly to students of medicine, whether *in posse* or *in esse*, but they may be perhaps of some interest also to the friends of those desirous of joining the ranks of the profession. Of all the learned professions that of medicine emphatically has the best claim to be called liberal and progressive. Those who aspire to live worthily in the discharge of its high duties must bring to the task a mind carefully trained and capable in various branches of intellectual activity. The best men in the profession are those of the widest culture who are able to bring to their work minds richly stored with the fruits of human energy garnered from many an extra-professional field. Ever since serious attention has been paid to the necessity of a carefully planned curriculum of medical education the possession of a sound preliminary education of a general nature has been recognised. Of late years the tendency has been to include in the preliminary examination subjects that would be of direct use to the student in his later career in the schools. It would be difficult to imagine a better training for a young man than that required in mastering the elements, say, of botany, zoology, and chemistry. At the outset of our remarks it has seemed natural to dwell upon the intellectual side of the career of medicine, for in that will be found a solace for the trials and difficulties that must be faced in that as in all other walks of life. From the monetary point of view, it is open to all men of ordinary gifts and application to secure a competency, although he may have at first to go through a more or less extended period of years spent in the weary task of waiting for practice. It is well to point out that under present conditions few may hope for the prizes that are met with in general, in consulting, in special, and, in some cases, in the army, navy, and civil services. Minor titles—that is to say, knighthoods and baroncies—are not conferred upon private practitioners, but are distributed to a moderate extent among the consultant, specialist, and official branches of the medical profession. The honour of a peerage was conferred upon the late Lord Lister, one of the greatest men who ever adorned the ranks of medicine, and one who has conferred upon mankind lasting and universal benefits. The student could not obtain a higher ideal of the humility and the genius of the true scientist than that afforded by a study of the life-work of Lister, nor could he find a more striking example of the vast field of possibilities that lies before the conscientious worker. At any moment the earnest student of medicine, be he legally qualified or not, may be the discoverer of some fact that may materially contribute to the progress of medicine and to the benefit of mankind. The majority of the medical practitioners, however, must needs be content with the sense of duty well and faithfully performed, without hope of wealth or social distinction. So far as private practice is concerned, the medical world is at present plunged in a state of doubt and difficulty. The passing of the National Insurance Act has disturbed their old relations with club and contract practice, and has

brought into that category a vast number of patients who formerly paid small fees for medical attendance. The terms offered by Government for administering medical benefits under the Act have been rejected by the medical profession as a whole. The upshot of the dispute it is at present impossible to forecast with any great amount of confidence. Should the Government accede to demands that appear to us not unreasonable, the position of the medical man who takes that kind of practice may be materially strengthened. There is one point, however, on which the student and the newly-qualified practitioner may be warned. Should the just demands of the profession be rejected it has again and again asserted in newspapers claiming to be officially informed that a large number of young medical men will be attracted by the income offered for insurance posts. It is to be hoped devoutly that the younger practitioners will not stultify the action of their elders by any such act of disloyalty. For the first time in history the medical profession has been brought together and has adopted a common action by the unanimous decision of a vast majority of its members. There are, unhappily, a few practitioners who do not see eye to eye with the majority in these matters, and it is to these men that Mr. Lloyd George and his colleagues will have to look for doctors willing to work the Act. We refuse to believe that any considerable number of the junior members of the profession will be so careless of the deliberate decision of their elders, or so short-sighted as to accept the posts in question. It is well that these things should be clearly understood by those who contemplate joining the ranks of a brotherhood which, if not rich in this world's goods, can never lose the distinction attached to an intellectual profession whose work forms part of the warp and the weft of human life. It is not too much to say that many of the happiest amenities of mankind's existence are due to the advances of scientific medicine, which has lengthened the average span of years and mitigated alike the horrors of war and the far more destructive evils inherent in the civil struggle for existence. What, indeed, can be thought of a science that has practically stamped small-pox, cholera, typhus fever, and plague from the face of the United Kingdom? What of the genius of our countrymen who have introduced chloroform and vaccination and aseptic surgery? What of the overflowing enthusiasm of the scientific workers ready to investigate any condition, from that of the humblest bacterial invasion of some denizen of a slum alley, to a deadly disease of the tropics, or elsewhere North, South, East or West of our great Imperial dominions?

From an early period of his studies, the student will do well to devote some attention to the wider aspects of professional work, for the real business of his life begins after the days of his probation. There are many ways in which the position of the medical practitioner might be greatly improved. Nor is it going too far to say that most of them would be attainable were a proper representative body created to protect the interests of the profession. One of the early questions that the student would do well to bear in mind is the relation the General Medical Council!

and the Medical Corporation he has joined will have towards his future career. Will they leave him in absolute neglect from the day of his final qualification, or will they do anything to help him on in the professional struggle? For some reason or other the profession is in the unstable position allotted in sacred writ to the house divided against itself. Instead of a single-portal entrance to the profession, as in law, we have a score or more of conflicting corporations. Indeed, the spirit of rivalry, and of individual as apart from collective action, seems to be so deeply rooted as to render the outlook for future consolidation somewhat discouraging. Yet the signs of the times do not point all in one direction. The British Medical Association, in spite of various defects and errors, has shown that great things are possible to a great profession with a common object in view. The success of many other purely professional organisations, moreover, points the moral of the tale sufficiently well to show that the road to professional paradise lies through the gate of co-operative union. Lastly, there is the recent opposition to the National Insurance Bill.

CHOICE OF A SCHOOL.

Manifold influences combine to make for the choice of a school. Tradition, family influence, proximity, means, and acquaintance with other students or members of the staff all come into play, and there are few who are not affected by them. The would-be student, however, who has the whole collegiate domain open to him and his selection unhampered by any consideration than that of merit, has the choice of nearly twenty centres at which to follow his bent. There is a natural tendency for a man to look to his immediate vicinity for the maturing of his genius, and in these days, when Universities are cropping up with bewildering prolixity, most students will probably find one within fifty or sixty miles of their homes. As the medical curriculum is laid down carefully by the General Medical Council, there is not much variation in that of the individual schools, and a good all-round education can be relied on in practically every one. On the other hand, some have teachers of established ability and reputation, whilst others are seeking to obtain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security of well-trodden paths. The object of this number of THE MEDICAL PRESS AND CIRCULAR is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, where rents are high, the cost of lodgings must be considerably more than in many smaller and less favourite towns, while, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a London Hospital as if he takes up his abode at a northern University. But, other things being equal, it is important for the average student to choose that school at which he is most likely in after years to obtain a resident post.

CHOICE OF A QUALIFICATION.

One day, in the not very distant future, we hope, the choice of what qualification to study for will not present so great a difficulty as it does to-day. Owing to the haphazard way in which British institutions and customs grow up, there have come into being a number of rival interests, both pecuniary and scholastic, which it is difficult to break down, with the result that students are offered all sorts of qualifying diplomas, conferring on them the right to append almost every conceivable alphabetical combination to their names.

It may be laid down in general terms that the shortest and least picturesque of these designations will generally be found the most serviceable, both from the expenditure of time that it will save in signing certificates, and in the greatest ease by which it will be understood of the people. Happily, or unhappily, a qualification even of the highest order has, as a rule, but small relation to success in practice, and many practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academical triumph.

COURSE OF STUDY.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the Universities are a little exacting in the number of special subjects they pile on to the crouching backs of their alumni, but in course of time it is generally found that the other centres of instruction follow their lead. Still, it is well to remember that from the moment the student pays his fee to the dean, the disposition of each moment of his time for the next five years is laid down with procrustean exactness, and that any diversion in the shape of amusement, illness, or failure in examination connotes a corresponding addition to the length of his pupilage.

THE ULTIMATE FUTURE.

Once qualified, a medical man can therefrom consult his predilections in some degree as to where he will practise his profession, though he will probably find the choice somewhat narrowed by the pecuniary resources at his disposal and the meagre opportunities offered for enterprise in the vicinity of popular, established practitioners. If he be averse from the struggle for existence in the troubled waters of private practice, he may turn to the comparative haven of competency afforded by the services. The Army, Navy, Indian, Colonial, and West African appointments may tempt him abroad, or the Poor-law infirmaries, lunatic asylums, public health officerships, or fever hospitals may prevail on him to remain at home. In all the official Government services there is a career with graduated promotion, and certain pension, whilst in the local services at home promotion is very uncertain, the pay, except in a few instances, very poor, and a pension either not provided or calculated on a studiously thrifty basis. One of the special advantages of medicine is that its votaries are nearly always sufficiently in request to be able to pick up a living as long as health lasts, and when old age comes on the practitioner will find that a parental Government is willing to pay him 5s. a week to the end of his days.

SUMMARY.

There are two types of men which find in medicine the most satisfying career. One is he who has a strong affinity for nature and natural phenomena. To such the profession of healing offers numberless opportunities for applying their peculiar powers, and gives much entertainment by the elusiveness of its secrets. The other class of man which finds satisfaction in the practice of medicine is he who regards the welfare of others before his own comfort and convenience. These rare beings, less rare probably in the medical profession than in any other, make devoted practitioners among the poor, and do not account their labour wasted if their patient gets well, but cannot afford through stress of illness to pay the bill. The man who does not get on well at medicine is he who wishes to account for all his services on a cash basis, and to make his practice a purely business concern. As a matter of fact, it is not possible to translate personal services into an exact money equivalent, and much unpleasantness pursues the path of him who tries to do so. The best that many men hope for is that a reasonable number of honest and grateful people will be found so far to appreciate his services that he is relieved of financial strain for the next half-year.

Medicine, then, is the means to an end, and that end is the amelioration of man's lot on earth, and not the aggregation of wealth. As the first it is a brilliant success; as the latter, it is a sorry business.

THE ENGLISH UNIVERSITIES.

THE English Universities are ten in number—*viz.*, Oxford, Cambridge, London, Manchester, Durham, Liverpool, Leeds, Sheffield, Birmingham and Bristol, beside the University of Wales. The choice of a University is usually determined by social, geographical, and financial considerations. Students whose parents are able and willing to incur the necessary expense will do well to select one of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial Universities.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, B.M. and D.M., two in Surgery, B.Ch. and M.Ch., and two diplomas, Public Health and Ophthalmology.

Graduates in Arts (B.A. or M.A.) are alone eligible, except for the Diploma Examinations. To obtain the B.M. and B.Ch. the following examinations must be passed:—1. Preliminary Mechanics and Physics, Chemistry, Animal Morphology, and Botany. 2. Professional. (a) First Examination: (1) Organic Chemistry, (2) Human Anatomy. (b) Second Examination: Subjects—(1) Medicine, Surgery, Midwifery, (2) Pathology, (3) Forensic Medicine with Hygiene and (4) *Materia Medica* with Pharmacy.

The First Examination for B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first, but Pathology and Hygiene may be taken before or with the remaining subjects. Before admission candidates must present certificates of attendance on a laboratory course in Practical Pathology and Bacteriology and of having acted post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination and the administration of Anæsthetics. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of D.M. is granted to Bachelors of Medicine of the University provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term.

Diploma in Ophthalmology.—There is an examination once in each year in the Theory and Practice of Ophthalmology for the purpose of granting certificates of proficiency therein, styled Diplomas in Ophthalmology. The examination is under the supervision of the Board of the Faculty of Medicine, which has power to make regulations as to the subjects of the examination, the time at which the examination is held, and the conditions of admission. No candidate is admitted to the examination for the diploma who has not pursued at Oxford a course of study in Ophthalmology approved by the Board of the Faculty of Medicine, and extended over a period of at least two months.

Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded

annually after an examination held in February. It is tenable for three years and is of the annual value of £200. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing and who have passed all the Exams. for the degree of B.M. or B.A. for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded annually in the subjects of Anatomy, Physiology and Pathology.

Detailed information may be obtained from the University Calendar.

UNIVERSITY OF CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry, (2) physics, and (3) biology; the second in (1) human anatomy and physiology, and (2) elementary pharmacology including pharmaceutical chemistry and the elements of general pathology; and the third in (1) surgery and midwifery, and (2) principles and practice of physics, pathology and pharmacology. The first examination is divided into three parts, and the second and third examinations each into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

New regulations for the Degrees of Bachelor of Medicine and Doctor of Medicine have recently been passed. Students who have not passed the 2nd M.B. Examination under the old regulations before December 31st, 1910, must proceed with their course under the New Regulations. Those who have passed the 2nd M.B. under the Old Regulations before December 31st, 1910, may proceed under either the old or the new Regulations. No examination under the old Regulations will be held after December, 1913. Copies of the New Regulations may be obtained on application to the Assistant Registrar.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every

candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a University Diploma testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually twice, in January and in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registrar, Cambridge. Full information is contained in the University Calendar.

UNIVERSITY OF LONDON.

The University of London became in 1900 a teaching as well as an examining body. The medical degrees awarded are those of M.D., M.S., and M.B., B.S., the two latter being now given together as a graduating degree. The medical degrees are granted to both internal and external students, the former being students of the constituent schools and colleges of the University.

The Matriculation Examination.—Students, before being admitted to the University, must either (1) have passed the Matriculation or the School Examination, or (2) have been exempted therefrom under Statute 116 of the University which recognises certain other examinations in its lieu. The examinations for matriculation take place three times in each year—in September, in January, and in June. Fee £2. If he withdraws before the last day of entry it will be returned to him. If he fails to present himself he will be allowed to enter for a subsequent Matriculation, within eight months, on payment of £1. If he retires after the commencement of the examination, or fails to pass it, the full fee of £2 is payable on every re-entry.

Provincial Examinations for Matriculation.—These are appointed by the Senate upon the application of any city, institution, or college desiring to be named as a local centre, and are carried on simultaneously with the examinations in London. Candidates must give notice upon their forms of entry to the Principal of the University, who will then make all necessary arrangements. Besides the University fee, a fee, usually varying from £1 to £3, is charged by the local authorities, and must be paid at the local centre immediately before the several examinations.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (Bachelor of Medicine and Surgery), and the higher separate degrees of M.D. (Doctor of Medicine) and M.S. (Master of Surgery). The curriculum for the medical degrees covers five and a half years, except in the case of students who have passed the Preliminary Scientific Examination or the First Examination for Medical Degrees, before July, 1910, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees.

The First Examination of Medical Degrees (Inorganic Chemistry, Physics, and General Biology) takes place twice in each year, commencing on the Monday following December 10th, and on the second Monday in July. The fee is £5 for each entry to the whole examination, provided that all the subjects are taken at one time. When less than the whole examination is taken at one time, it is £2 for each subject. Candidates must, at their first entry, present themselves in all three subjects; if failing in one subject only, they may, with permission, present themselves for re-examination in that subject on payment of the proper fee.

The Second Examination for Medical Degrees (Part I.): Organic Chemistry.—This examination takes place twice in each year. No candidate will be admitted to this examination within six months of having passed the First Examination. The fee is £2 for the first and every subsequent entry. The examination will consist of a paper and practical work, and may include oral questions in

Organic Chemistry, which is "to be treated in an elementary manner, and with special regard to its applications in physiology, pharmacology, and pathology."

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing in 1911 on the second Monday in March, and on the first Monday in July. The subjects of the examination are Human Anatomy and Embryology, Physiology, and Pharmacology, including Pharmacy and *Materia Medica*. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees. The fee for each entry to the whole examination is £8. For re-examination in one subject it is £4.

M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups, namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The fee is £10 for each entry to the whole examination, and £5 for examination or re-examination in either group. There will be no separate examination held for Honours, but the list of candidates who have passed will be published in two parts, namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the degrees of M.B., B.S. not less than two years previously, but for those who have taken the M.B., B.S. degrees with honours, or have done certain original work, this period of delay may be reduced to one year. Candidates who have obtained their M.B. degrees in or before May, 1904, will not be required to hold the degree of B.S. before seeking the doctorate. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners, the candidate may be exempted from the written examination in that subject. The fee is £20, and for re-examination £10.

Master in Surgery.—The examination takes place twice in each year, and commences on the first Mondays in December and July. Candidates must produce certificates of having taken the degrees of M.B. and B.S. not less than two years previously (with certain exceptions, as in the examination for the M.D.) and of having subsequently held for at least six months a resident or non-resident Surgical hospital appointment. The fee is £20, and for re-examination £10.

Full details can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. Students should apply direct to the University for this detailed information.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—*FACULTY OF MEDICAL SCIENCES.*—The Faculty of Medical Sciences comprises Physics, Chemistry, Botany and Zoology, also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Departments of Hygiene and Public Health, of Pathological Chemistry, and of Experimental Neurology (Post-graduate Study). Full Preliminary and Intermediate Courses of study are provided for

students desirous of obtaining the medical degrees of the University of London and as well as for students seeking the qualifications of other Universities and licensing bodies. University and King's Colleges have been constituted University Centres for the teaching of the Medical Sciences. A student can enter the College directly, and at the end of the first and second courses select the Medical School and Hospital.

Scholarships and Exhibitions.—Five annual University Entrance Exhibitions of £40 a year, six similar scholarships of £50 a year each in science subjects are annually awarded, and three Andrews' Entrance Scholarships. The Bucknill Scholarship of 135 guineas and two Exhibitions of 55 guineas are awarded on the results of an examination held in July. The Cluff Memorial Prize, value £15, is awarded for proficiency in Anatomy, Physiology, and Chemistry; the Schäfer Prize in Physiology, value £18, for proficiency in Physiology; the Sharpey Physiological Scholarship, value £150, for Research in Physiology.

Composition Fees.—Course for the first Medical Examination, 26 guineas; course for the second Medical Examination, 58 guineas; course for the first Examination of the Conjoint Board, 21 guineas; course for the second Examination of the Conjoint Board, 58 guineas.

The London Medical Schools recognised by the University with the title of "University of London," are:—University College, King's College, St. Bartholomew's Hospital Medical School, St. Thomas's Hospital Medical School, Westminster Hospital Medical School, Guy's Hospital Medical School, London Hospital Medical College, Middlesex Hospital Medical School, Charing Cross Hospital Medical School, St. Mary's Hospital Medical School, Royal Army Medical College, London School of Tropical Medicine, School of Medicine for Women, and the Lister Institute of Preventive Medicine.

UNIVERSITY OF LONDON—KING'S COLLEGE, LONDON, STRAND.—In the medical division of the Faculty of Science students are prepared for their first examination (Chemistry, Physics, Biology), and for their second examination (Anatomy, Physiology, and Pharmacology), by the University Professors attached to King's College, London, and their assistants. At present four medical schools, viz., those attached to King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital, the teaching in which is restricted to the subjects of the final examinations, send their students to King's College for the purpose of tuition in the above-mentioned preliminary and intermediate studies. Full particulars as to courses of study, laboratory accommodation, hours, fees, etc., can be obtained on application to the Dean, Professor Halliburton, or the Secretary, Mr. Walter Smith, at the College.

UNIVERSITY OF DURHAM.

Two diplomas, one Licence and six degrees in Medicine and Hygiene are conferred—viz., the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor in Medicine, Bachelor of Hygiene, and Doctor of Hygiene, Diploma in Public Health and Diploma in Psychiatry and the Licence in Dental Surgery. These degrees, diplomas and licence are open to both men and women.

For the degree of Bachelor of Medicine (M.B.), there are four professional examinations. The subjects are: Elementary anatomy, biology, chemistry, and physics. For the second: Anatomy and physiology. For the third: *Materia medica* and pharmacy, pathology and elementary bacteriology, medical jurisprudence and public health; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children, and clinical gynaecology.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Victoria Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply

with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor of Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master of Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor of Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

For the degree of Doctor of Medicine (M.D.) candidates must be not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must present an essay which has been prepared entirely by himself (and typewritten), based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

A new wing has been added to the College of Medicine to accommodate the departments of physiology and bacteriology. It also contains students' union rooms and gymnasium.

The New Royal Victoria Infirmary, containing 400 beds, was opened by the late King, in July, 1906. In the new infirmary adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Maternity Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to students, whilst the scholarships available are numerous and of considerable value.

Fees.—(a) A composition ticket for lectures at the college may be obtained—1, By payment of 72 guineas on entrance, 2, By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year, 3, By

three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. A Composition Ticket for the course of lectures and practical work of the first two years of the curriculum may be obtained by the payment of 40 guineas on entrance. (b) Single courses of lectures, five guineas. (c) Fees for attendance on hospital practice: For three months' medical and hospital practice, six guineas; for six months, ten guineas; one year, fifteen guineas; composition fee in one payment, thirty-five guineas; or by two instalments—*viz.*, first year, twenty guineas; second year, eighteen guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary. (d) Composition fee for lectures, &c., at the College for the Licence in Dental Surgery, 34 guineas. Composition fee for dental practical work at Newcastle Dental Hospital, 35 guineas.

A Licence in Dental Surgery has been instituted. Before admission to the Final Examination, each candidate must furnish evidence, (1) of having attained the age of 21 years, (2) of having undergone a three-years' pupillage in mechanical dentistry with a registered dentist, and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. He must also sign such declaration as the University may determine, binding himself not to advertise for professional purposes. Examinations are held concurrently with the medical examinations, and the fees payable by candidates amount to £15.

The Senate of the University has decided to grant a Diploma in Psychiatry, full particulars of which may be obtained from the College Calendar.

Further particulars will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

MANCHESTER UNIVERSITY.

Candidates for degrees in medicine and surgery (M.B., Ch.B., M.D., Ch.M.) must attend classes in the University during at least two years, and for three years must pursue a course of medical study at any college or medical school recognised by the University.

They are required to have passed the Matriculation Examination, or such other examination as may from time to time be recognised for this purpose by the University. The Matriculation Examination is held in July and in September.

Before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities. All candidates for these Degrees must have attended approved courses of both lectures and laboratory work, and must pass four examinations.

The final examination cannot be taken before the fifth year of medical study. The subjects of examination are as follows: 1, Medicine, systematic and clinical, including mental diseases and diseases of children; 2, Surgery, systematic, clinical, and practical; 3, Obstetrics and diseases of women; 4, Forensic medicine and toxicology.

The regulations relating to the M.D. and Ch.M. Degrees can be obtained on application to the Registrar.

The first M.B. and Ch.B. is held in March, July, September, and December. The second examination is held in December, and in March; the third examination in March, July and December; the Final in July and December; the examination for Ch.M. in July only.

Fees.—Matriculation examination, £2, subsequent examination in the same year, 30s. First examination, £5; for any subsequent examination, £2. The fees for the Second Examination and for the Third and Final Examinations are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £5 on the conferring of the degree of Ch.M.

The buildings include large laboratories, dissecting-rooms, library and reading-rooms, and are on the most modern principles. Students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the com-

plete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 592 beds. The Cheadle Lunatic Asylum, St. Mary's Hospitals, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The numerous appointments are of considerable monetary value. The principal are:—The Leech fellowship of £100; Honorary Research Fellowships; Junior Research Fellowships in Public Health, two of the value of £50, each annually; Entrance scholarships in medicine, £100 (towards University and Infirmary fees); Ashby Memorial Research Scholarship in Diseases of Children, £100, awarded triennially; Dreschfeld Memorial Scholarship £30, awarded annually; Turner Medical scholarship of £20 to students who have completed a course of medical study in the University; Robert Platt physiological scholarship of the value of £50; Robert Platt zoological and botanical scholarship, £50; Professor Tom Jones memorial surgical scholarship of £100, awarded triennially; two Dauntsey medical scholarships, one of £45 and one of £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25, awarded annually; and many prizes. Robert Platt Exhibitions in Physiology, £15, awarded annually; Robert Platt Biological Exhibitions, £15, awarded annually; Sidney Renshaw Exhibitions in Physiology, £15, awarded annually; Professor Tom Jones Exhibition in Anatomy, £25, awarded annually.

Fees.—For courses of instruction for the degrees of M.B. and Ch.B., of the University:—For the first M.B. examination the total cost amounts to about 30 guineas payable on entry. A composition fee of 70 guineas, payable in three instalments of 30, 20, and 20 guineas, at the commencement of the second, third, and fourth years of studentship respectively, admits to the courses of instruction required for the degrees of M.B. and Ch.B.

Dental Fees.—The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, and for candidates for the University diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants Degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these Degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge; (b) Responsions of the University of Oxford; (c) The matriculation examination of any recognised University; (d) The leaving certificate (higher) of the Oxford and Cambridge Boards; (e) The Oxford or Cambridge senior local examination.

Matriculation Examinations are held in July and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher Degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery

(L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital.

THE GENERAL AND QUEEN'S HOSPITALS.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the University Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 500 beds. 8,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Peter Thompson, Dean of the Medical Faculty.

THE UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Hygiene (M.H.). The course of study for the Degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

The degree of M.H. is given after two years' study and examinations, and includes the D.P.H.

Diplomas.—Diplomas have been instituted in Public Health (D.P.H.), Ophthalmic Surgery (D.Ch.O.), Tropical Medicine (D.T.M.), and Veterinary Hygiene (D.V.H.). Special diplomas are also granted in Anatomy, Bacteriology, Bio-chemistry, and Parasitology after a course of study of three terms in the subject chosen and allied subjects.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees, diplomas and qualifications of the other licensing bodies.

Hospitals.—The Clinical School of the University consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1,127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an unrivalled field for clinical education and study, and all are within easy access from the University. The period of hospital practice extends over the last three years of medical study. There are a large number of appointments to House Physicianships and Surgeonships both at the general and special hospitals, which are open to qualified students of the School. These appointments (20) in most cases carry salaries varying from £60 to £100 per annum.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £1,000 are awarded annually. A Holt Fellowship in Pathology, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology, of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynaecological Pathology (£100 a year, renewable). A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. Two Lyon Jones scholarships, of the value of £21 each for

two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, Materia Medica, and Pharmacology. A University Scholarship of £25 awarded on the results of the second examination for the degree. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. A Clinical School Exhibition of £15 awarded under similar conditions. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the First M.B. Course for the University Degree in Medicine.

The University also grants a Diploma in Dental Surgery (L.D.S.) and Degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes walk from the Dental Hospital.

Communications should be addressed to the Dean, Mr. K. W. Monsarrat, F.R.C.S., the University, Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THE DIPLOMA OF TROPICAL MEDICINE, UNIVERSITY OF LIVERPOOL.—The school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. The instruction given occupies six hours a day for five days a week during thirteen weeks. Each Course consists (1) of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on special African and other diseases delivered at the University; (3) of systematic lectures and demonstrations on tropical pathology, parasitology and bacteriology by the Walter Myers Lecturer, at the University; (4) of similar instruction on medical entomology by the Lecturer on Economic Entomology at the University; (5) of clinical lectures and demonstrations delivered at the Royal Southern Hospital by the Physician in charge of the Tropical Ward, the Professor, and the Walter Myers Lecturer; and of lectures or demonstrations by assistant teachers.

In December and April an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days, and consists (1) of papers on tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination.

The fee for the full course of instruction is thirteen guineas, with an extra charge of ten shillings and sixpence for the use of a microscope, if required. The fee for the examination is five guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool, from whom prospectuses may be obtained.

Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for Research work is to be had, both at the University laboratory of the school, and at its Research Laboratories at Runcorn (sixteen miles distant from Liverpool).

Since it was instituted ten years ago the school has employed thirty different investigators paid out of its funds, and has despatched to the tropics twenty-one scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs with many plates and figures, besides

text books and numerous articles in the scientific press. From the beginning of 1907, however, the Memoirs have been succeeded by the Annals of Tropical Medicine and Parasitology, published by the Committee, and open to outside contributors. (Apply to the Secretary, B10, Exchange Buildings, Liverpool). The Mary Kingsley Medal is awarded by the School for distinguished work in connection with tropical medicine, and has been given to Colonel Bruce, Professor Koch, Dr. Laveran, Sir Patrick Manson, Lord Lister, Professor Looss, Professor Danielewsky, Dr. Charles Finlay, Mr. W. M. Haffkine, Professor Golgi, Colonel Gorgas, Professor Theobald Smith, and Rt. Hon. Joseph Chamberlain, M.P., and others.

UNIVERSITY OF BRISTOL.

The University grants the conjoined degrees in the Faculty of Medicine of M.B., Ch.B., the degree of Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.); also diplomas in Public Health (D.P.H.), in Dental Surgery (L.D.S.), and in Veterinary State Medicine (D.V.S.M.).

The conjoined Degrees of M.B., Ch.B.—The curriculum occupies five years and a half. The University lectures and laboratory courses are attended in the large and well equipped new wing of the University. Hospital practice and Clinical instruction are provided in the allied hospitals, which together afford upwards of six hundred beds and a very large external midwifery department. Three years at least must be spent in the University, and two of them subsequently to passing the second examination.

Degree of B.D.S.—The curriculum occupies five years. Mechanical Dentistry may be studied in the new and well equipped University Laboratory under the supervision of a skilled mechanic. In this laboratory the whole of the mechanical work for both the Bristol Royal Infirmary and the Bristol General Hospital is done by the pupils. Lectures and ordinary laboratory work are attended in the University, the Metallurgical laboratory is in the Chemical department, and has been specially fitted for the purpose. Prosthetic and operative work are done in the Bristol Royal Infirmary and the Bristol General Hospital, and special Dental House Surgeons have been appointed to amplify the instruction given by the staff.

Diploma in Dental Surgery, L.D.S.—The curriculum occupies four years, and runs on very similar lines to that for the B.D.S. It is not, however, necessary to pass the matriculation examination, and some subjects required for the degree are omitted. Candidates for either the B.D.S. or L.D.S. must be registered Dental students.

Diploma in Public Health.—The necessary laboratory work is done in the University in the Chemical and Pathological departments. The remainder of the curriculum is taken under the Medical Officer of Health for the City and County of Bristol (Lecturer in Public Health) and the Assistant Medical Officer for the Port of Bristol (Demonstrator in Public Health).

N.B.—Although the various courses are primarily designed for the University degrees and diplomas, equal attention is paid and equal facilities are offered to students who enter for the degrees of other Universities, such as the University of London, and for the diplomas of the various examining bodies.

Women are admitted to all degrees and diplomas, and to the courses of study necessary for them. The University Hall of Residence is situated at Clifton, within a short distance of the University. Particulars of residence may be obtained from Miss M. C. Staveley, M.A., at the University.

Inclusive Fees.—For the M.B., Ch.B. curriculum, 140 guineas; for the B.D.S. curriculum (including mechanical pupilage), 190 guineas; for the B.D.S. curriculum (excluding mechanical pupilage), 115 guineas; for the L.D.S. curriculum (including mechanical pupilage), 168 guineas; for the L.D.S. curriculum (excluding mechanical pupilage), 93 guineas; for the D.P.H., 27 guineas. Arrangements can be made for paying these fees by instalments.

Further information can be had from the Dean of the Faculty (Professor E. Fawcett) or from the Registrar of the University.

Appointments (Undergraduate).—Clinical Clerkships, Dresserships, also Ophthalmic, Obstetric, and Pathological Clerkships are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the Dressers reside in rotation free of charge.

Appointments (Post-Graduate).—At the Bristol Royal Infirmary:—Two House Surgeons, £100 each per annum; two House Physicians, £100; Resident Obstetric and Ophthalmic House Surgeon, £75; Throat, Nose, and Ear House Surgeon, £75; Casualty Officer, £50; Dental House Surgeon, £100. All these appointments are made for twelve months, except that of Casualty Officer, which is for six months. From the resident officers a Senior Resident Officer is appointed at an additional salary of £30. At the Bristol General Hospital:—Senior House Surgeon, £150 per annum; Casualty House Surgeon, £100 per annum if another resident appointment has been previously held; two House Physicians, £80; House Surgeon, £80; Dental House Surgeon, £200 per annum. All these appointments are for six months, except that of Dental House Surgeon, which is for two years.

The Winter Session opens on October 1st.

UNIVERSITY OF LEEDS.

The school of medicine attached to this recently incorporated University, was originally founded eighty years ago as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened fourteen years since, contains one of the finest dissecting-rooms in the United Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 524 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken. Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, a hospital for women and children, and a maternity hospital, all of which are open to students of the school.

Scholarships, Prizes, &c.—(1) An entrance scholarship of £73 2s. 6d. There is also a Hardwick prize in clinical medicine, a McGill prize in clinical surgery, each of the value of £10. Thorp scholarship of about £25 a year in forensic medicine and hygiene, and a Scattergood prize of £5 in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is £73 2s. 6d. for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

The composition fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the University.

Degrees and Diploma in Dental Surgery are obtainable at this University, being Bachelor of Dental Surgery (B.Ch.D.), and Master of Dental Surgery (M.Ch.D.). Candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been

passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not attained the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction, approved by the University, extending over not less than four years, two of which must be spent in the University, and that they have completed a pupilage of three years, two of such years at least having been taken before the First Professional examination. Candidates are required to satisfy the Examiners in the several subjects of the following examinations: A preliminary examination in Arts; a Preliminary examination in Science; the First Professional examination; and the Final examination.

A Diploma in Public Health (D.P.H.) is granted after examination under the usual regulations, also a Diploma in Psychological Medicine.

UNIVERSITY OF SHEFFIELD.

By the Charter granted in 1905, this University is permitted to grant degrees in medicine. All its courses and all its degrees are open, without restriction, to both sexes. The new buildings of the University, opened by his late Majesty King Edward in 1905, are situated at the west end of the city, overlooking on two sides the adjoining Weston Park. The medical department occupies the entire north wing of the University quadrangle, and is within easy reach of the various hospitals, with which it is connected for clinical purposes.

These are as follows:—The Royal Infirmary contains 320 beds, with an annual average number of over 3,800 in-patients, over 11,500 out-patients, and over 23,000 casualties; the Royal Hospital, with 190 beds, and an annual number of over 3,000 in-patients, over 20,000 out-patients, and nearly 20,000 casualties; the Jessop Hospital for Diseases of Women, with 80 beds, about 750 in-patients, and over 3,000 out-patients; also a Maternity Department, with about 450 in-patients per annum, and about 700 out-patient cases attended. Special courses on fevers are held at the City Fever Hospitals (570 beds), and on Mental Diseases at the South Yorkshire Asylum (1,610 beds).

Clinical Practice.—The practices of the Royal Infirmary and Royal Hospital are amalgamated for the purpose of clinical instruction, giving a total of 510 beds for the treatment of medical, surgical and special cases.

Appointments.—The following are open to all students who have passed their examinations in anatomy and physiology:—Casualty Dresserships, Surgical Dresserships, Medical Clerks, Pathological Clerks, Ophthalmic Clerks, Clerk to the Skin Department, etc.

Fees.—Composition fee of £80, payable in three instalments, viz.:—£24 at commencement of first year of study; £28 at commencement of second year of study; £28 at commencement of third year of study. This composition fee entitles the student to attendance on all the courses of lectures and practical classes, except pharmacy, vaccination, and instruction in anæsthetics required for a degree course in the University, or for the ordinary qualifications in medicine and surgery of the examining boards.

Composition Fee for Medical, Surgical, Gynaecological and Obstetrical Hospital Practice.—Fee for the full period of hospital practice required by the examining boards:—If paid in one sum at commencement of hospital practice, £42; or if paid in two sums of 21 guineas and 20 guineas, one on beginning hospital practice, the other twelve months later, £43 rs.

Dental Department.—In connection with the University there is a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here.

Scholarships and Fellowships.—Entrance Medical

Scholarship of the approximate value of £122, open to both sexes, awarded in June each year. Four Town Trustees' Scholarships, value £50, tenable for three years. Town Trustees' Fellowship, value £75, open to graduates of the University, tenable for one year. Mechanics' Institute Scholarship, value £50, tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50 per annum, tenable for two years, open to graduates of the University; and the Kaye Scholarship, value about £22 10s. A Gold Medal is offered annually for the best student in clinical medicine and clinical surgery. A Bronze Medal is awarded annually to the student who has gained first place in the examination for the full course in each year.

Degrees.—Candidates for a medical degree must have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the matriculation examination, or its recognised substitute. The degrees in medicine obtainable are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); conditions and particulars of which may be obtained on application to the Dean.

At the University of Sheffield post-graduate courses are held annually. These courses are specially arranged for practitioners, and the work done is mainly clinical and practical.

A Diploma in Public Health is also granted by the University.

UNIVERSITY OF WALES.

The School of Medicine, in University College, Cardiff, which is one of the constituent colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific Examination of the University of London, and for the corresponding examinations of other licensing bodies. Chairs of Anatomy, Physiology and Pathology and Bacteriology and Lectureships in Materia Medica and Pharmacy and Histology and Embryology have been established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of King Edward VII's Hospital, Cardiff, give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent at least three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the First and the Second Examinations for Medical Degrees of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £63, or by paying £20, £28 and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for the diploma in Public Health and Hygiene of the University of Wales can attend complete courses of

lectures and laboratory instruction in this department. These courses are also recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, by Victoria University, and other Examining Boards.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England

Courses of lectures to midwives, adapted to the requirements of the Central Midwives Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

Scholarships and Free Studentships.—The attention of students about to matriculate is drawn to the entrance scholarships and Free Studentships which are offered at the college for competition in April, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

THE ENGLISH COLLEGES.

THE medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.

CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations are held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates. The subjects of the first professional examination are Part I., Chemistry; Part II., Physics; Part III., Elementary Biology; and Part IV., Practical Pharmacy. Candidates may present themselves immediately after passing the preliminary examination in general education, provided they are able to produce the certificates required. They must present themselves for examination in Parts I. and II. together, until they have reached the required standard to pass in both or in one of these parts, but they will not be allowed to pass in one part unless they obtain at the same time at least half the number of marks required to pass in the other part. Candidates may take Parts III. and IV. separately, or they may present themselves for the whole examination at one time. Practical Pharmacy may be taken with, or at any time before Part I. of the Final Examination. Candidates who shall produce satisfactory evidence of having passed an examination for a degree in medicine in any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which they have passed.

The fee for admission to the first examination is as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Parts I. and II., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in

both subjects at one and the same time. The study of anatomy and physiology will not be recognised until candidates have passed in two of the first three parts of the first examination. Candidates will be admissible to the second examination fifteen months from the date of passing the required subjects of the first examination.

Candidates referred to the second examination will be required, before being admitted to re-examination, to produce certificates that they have pursued, to the satisfaction of their teachers, in a recognised place of study, their anatomical and physiological studies during a period of not less than three months subsequently to the date of their reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:

—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynaecology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time, provided that Midwifery may not be taken until the whole curriculum is completed.

Fees for admission to the third or final examination are as follows:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynaecology, £3 3s.

Candidates referred on the third or final examination, or on one or more of the three parts into which they may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher. A candidate who possesses a registrable qualification is admissible to re-examination without producing additional certificates.

REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN

CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom and Graduates of Medicine of certain recognised Colonial or Foreign Universities, are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEMBERS.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have

passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 15s. is deducted. In either case £6 6s. has to be paid before examination.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEMBERSHIP.—The candidates are now subject to the regulations of the Conjoint Board.

FELLOWSHIP.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

The diploma of Fellow is granted to successful women candidates subject to the provisions of the Medical Act, 1876, and of the Bye-Laws of the College.

FEES.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Examining Board in England, Examination Hall, Queen Square, Bloomsbury, London, W.C.

SOCIETY OF APOTHECARIES OF LONDON.

PRIMARY EXAMINATION.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, *Materia medica*, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, except the month of September, and is divided into Sections 1 and 2.

Section 1 consists of three parts:

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of commencement of medical study.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

FEES.—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

ST. BARTHOLOMEW'S HOSPITAL.—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, public health, chemistry, biology, physics, and chemical pathology, and two additional operation theatres have just been built. A new block of buildings has recently been completed at a cost of £120,000, and contains new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining hall and a common-room for students, &c. A second new block, devoted to pathology, and containing extensive laboratories for bacteriology, clinical pathology, pathological histology, chemical pathology, etc., has also been constructed. Collegiate residence is permissible, subject to the ordinary rules.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat and nose are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and assistant surgeons, and to the physicians and surgeons in charge of special departments, are appointed every three months without fee.

Scholarships, &c.—There are three open scholarships in science, £75, £75, £150, tenable for one year, and an Entrance Scholarship in Arts, value £100, and the Jeaffreson exhibition, value £50; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, two Brackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize;

Holden Research Scholarship in Surgery, value £105; Lawrence Research Scholarship and gold medal, value £115 for pathology.

Composition Fees.—(1) For students commencing their medical studies, one sum on entrance, 165 guineas; or by four instalments of 45 guineas. (2) For students who have passed an examination in preliminary science, in one sum on entrance, 145 guineas; or by instalments. (3) For students who have finished two years of medical study but have not passed an examination completing their anatomical and physiological studies; if paid in one sum on entrance, 110 guineas; or by annual instalments. (4) For students who have completed three years of medical study but have not passed an examination in anatomy and physiology, 90 guineas; or by annual instalments. (5) University students who have passed an examination completing their anatomical and physiological studies, in one sum, 80 guineas; or by instalments.

Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas. Fuller details will be supplied on application to the Dean.

CHARING CROSS HOSPITAL.—The School attached to this Hospital is situated in Central London, and contains new pathological and bacteriological laboratories, pharmacological, *materia medica*, and public health, laboratories, theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special departments, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen and electrical departments.

The school arranges for a complete education in all departments, with special teachers for all preliminary and intermediate subjects.

By arrangement with the University of London, all students for the Primary and Intermediate portions of the curriculum carry out the necessary courses of instruction at King's College Laboratories, situated within a few minutes' walk from the Hospital. The entire teaching of the school is devoted to pathological, clinical and other subjects of final studies.

Appointments.—Salaried resident medical officer, medical and surgical and obstetric registrars (annual). Twelve resident house physicians, twelve house surgeons, and two obstetric officers are appointed each year, after competitive examinations.

Fees.—The fees for the five years' curriculum may be paid either by composition fee, in one sum, on joining, or by sessional payment system.

London University Student.—10 guineas entrance, and 25 guineas annually. Composition fee (5½ years) 120 guineas.

Conjoint Diploma Students.—10 guineas entrance, 22 guineas annually. Composition fee (5 years), 110 guineas. Payment may also be made for individual classes and hospital practice when taken separately.

Final Students.—Students of any university in the United Kingdom who have passed the examinations in anatomy, physiology, chemistry, and other preliminary subjects, may here complete their studies on payment of an annual fee of 25 guineas, or of 55 guineas (3 years' course) in one sum.

The fees for *Dental Students* for the two years' curriculum may be paid:—(a) in one sum of 45 guineas on entry (2 years' course); (b) in two instalments—one of 27 guineas on entry, and the second of 22 guineas at the commencement of the second twelve months.

Prospectus and further information can be obtained on application to the Dean (Dr. William Hunter, F.R.C.P.), Charing Cross School, Chandos Street, Strand.

ST. GEORGE'S HOSPITAL.—This hospital is situated in the West End, facing Hyde Park, and is readily accessible from all parts of London or the suburbs. It has recently undergone extensive alterations and improvements, has a service of 436 beds, of which 100 are at the Atkinson-Morley Convalescent

Hospital at Wimbledon, and contains special wards for ophthalmic cases and diseases of women.

Appointments.—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of £100; a medical registrar, with a salary of £200 per annum; a surgical registrar with a salary of £200 per annum; a resident anaesthetist with a salary of £100 per annum; an administrator of anaesthetics with a salary of £50 and two with salaries of £30 per annum. All offices are open to candidates without additional fee.

There are two Scholarships open to University students, of 70 guineas and £50, particulars of which will be furnished by the Dean.

An *Athletic Ground* of 14 acres, in the grounds of the Convalescent Hospital at Wimbledon, has recently been acquired, and a football ground and tennis courts have been laid out.

Fees.—For first year, £21 or £26 5s., according to the course. For second and third years, £63 in two instalments. Students entering their names on the books before commencing the preliminary or intermediate subjects pay no entrance fee. Fees for clinical students: Entrance fee, 10 guineas; annual composition fee, 30 guineas.

GUY'S HOSPITAL.—This hospital is situated on the South side of London Bridge, and contains 617 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study including the pupilage in mechanical dentistry within the walls of one hospital will be appreciated by those intending to practise dentistry.

Appointments.—Eight house surgeons, eight house physicians, sixteen out-patient officers, sixteen assistant house surgeons, twelve obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £120 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in *materia medica* (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150. The Arthur Durham travelling scholarship of the value of £100, triennially; Greville Research Scholarship,

£200 annually; Oldham Prize in Ophthalmology, £30 annually.

Fees.—A new system for payment of composition fees has been instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

KING'S COLLEGE HOSPITAL.—The hospital is situated close to the Royal College of Surgeons, Lincoln's Inn. There are 220 beds. The student, who pays a composition fee for the whole medical curriculum, carries out his preliminary and intermediate medical studies at King's College, Strand, and enters the hospital when he has passed his examination in anatomy and physiology. The hospital contains special beds for diseases of women, children, eye, ear and throat cases. There are also dental, skin, X-ray, and photographic departments. There are well-equipped pathological laboratories, and the collection of pathological specimens has recently been moved from King's College to the hospital. The various athletic clubs, students' societies, and the Common Room are now under the management of the Clubs and Societies' Union.

Scholarships.—Four of £50: one in arts and one in science, and two entrance scholarships for university students; a senior scholarship for fifth year students, and many special and class prizes are open for competition amongst students.

Appointments.—Senior medical, surgical and obstetric tutorships, Sambrooke medical and surgical registrarships, tenable for two years, each £50 per annum. Resident hospital appointments—*viz.*, senior and junior house physicians, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; house anaesthetist; and senior and junior clinical assistants in special departments every six months.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained post free from the Dean, Dr. H. Willoughby Lyle, or the Secretary, Clifton Kelway, Esq., King's College Hospital Medical School, Lincoln's Inn Fields, W.C.

Fees.—The fees payable by full students for the Course of Advanced Studies, whether for the University Degrees or for the Examinations of the Conjoint Examining Board, are: 80 guineas if paid in one sum; 82 guineas if paid in instalments, as follows: 10 guineas at entrance; first payment, 40 guineas on entering the Hospital; 32 guineas at commencement of second year.

These fees also include membership of the Hospital Clubs and Societies' Union for three years.

Composition fees have been arranged for the complete medical courses.

- (1) University of London Course, including the Preliminary Scientific, Intermediate, and Final Course. Fee, 150 guineas.
- (2) Conjoint Examining Board Course, including the courses for the 1st, 2nd, and 3rd examinations. Fee, 150 guineas.

THE LONDON HOSPITAL.—This hospital is the largest in Great Britain, containing, as it does, 922 beds. It has, moreover, wards and a teaching staff for every special department in the domain of medicine; the scholarships and prizes are many and valuable.

Appointments.—The salaried appointments open to students are those of medical registrars three, surgical registrars three, obstetric registrars one, medical, surgical, and obstetric tutors; senior dressers to outpatients; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments. There are also five resident house physicians and eight resident house surgeons, two accoucheurs, seven receiving-room officers, two emergency officers, and three pathological assistants. Also unpaid clinical assistantships in the various special departments. In addition there are numerous assistantships and clerkships, and dresserships in the various departments.

Scholarships and Prizes.—At Entrance: Price scholarships in science, £100; in anatomy and physio-

logy, £52 10s.; entrance scholarships in science, £50; Epsom scholarship, £126; Buxton scholarships in arts, £31 10s. After Entrance: anatomy and physiology prize, £25; Letheby prizes, £25; prizes in clinical medicine, surgery and obstetrics, £20 each; Duckworth Nelson prize, £10; Hutchinson prize, £40; Sutton prize, £20; Sir Andrew Clark prize, £26; Anderson prizes, £9; dressers' prizes, £40; practical anatomy prizes, £10; Dourro Hoare prize, £5; Wynne Baxter prize, £5 5s.

A special course for the D.P.H. will commence at the beginning of the winter session.

Special classes for the 1st and 2nd M.B.Lond., the primary and final Fellowship, and other examinations are held. Those for the final and primary F.R.C.S. commence on September 2nd.

Fees for Full Course.—Entrance Fee 20 guineas; annual Fee 30 guineas.

Special entries can be made either for single courses of lectures or for hospital practice. The Students' Hostel has recently been extended. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train.

The Dental School attached to the Hospital will be opened on October 2nd. The Course of Instruction covers the full curriculum for the Dental Diploma.

Fuller particulars can be obtained of the Dean, William Wright, M.B., D.Sc., F.R.C.S.

ST. MARY'S HOSPITAL.—This Hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 301 beds, of which 31, recently opened in the Clarence Wing, are devoted to treatment by Therapeutic Inoculation. An additional Operating Theatre has recently been opened in this wing. The Inoculation Department, instituted in 1906, has greatly expanded, and occupies a series of rooms in the New Wing of the Hospital.

The Department is under the personal supervision of Sir Almroth Wright, F.R.S.

During the present year a new Casualty Department has been opened, with increased accommodation.

The Athletic Ground is situated at Park Royal, Acton, within easy reach of the Medical School. This provides ample accommodation for the various athletic clubs, and possesses a good pavilion.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, two resident anaesthetists, and two resident medical officers to the inoculation wards are appointed in each year, and receive board and residence in the Hospital.

Scholarships, &c.—One scholarship in natural science of the value of £100, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship of the value of £50 and one of the value of £26 5s., under the same conditions. Two scholarships, each of 50 guineas, open to University Students. The scholarships will be awarded by examination on September 23rd, 24th and 25th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 65 guineas in one sum, or 70 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

Complete Curriculum.—The Medical School provides complete instruction for the various medical degrees and diplomas, including courses of preliminary scientific and intermediate subjects, which are recognised by the University of London as approved courses for internal students. Students may join in October, January, or April.

THE MIDDLESEX HOSPITAL.—The Hospital and Medical School are situated in Mortimer Street, at the top of Berners Street, and only a few minutes' walk from Goodge Street station (Hampstead and Charing Cross Tube), Oxford Circus stations (Bakerloo and Central London Tubes), and Portland Road station (Metropolitan station).

The Hospital contains 440 beds, including special wards for cancer cases, maternity and gynaecological cases, and for diseases of the skin and eye. The cancer wing (containing 90 beds) and special investigation laboratories offer unrivalled opportunities for the study of cancer, both in its clinical and pathological aspects. In the electro-therapeutical department students obtain instruction in the treatment of lupus and cancer by the X-ray method.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health. Ample laboratory and class-room accommodation is provided, and there is a clinical laboratory where every facility is given for original research. Special classes are held to prepare students for the intermediate examinations of the Universities, and for the primary and final examinations for the F.R.C.S. (England) Diploma. There is a residential college in the hospital for a limited number of students.

Hospital Appointments.—All appointments are made without fee of any kind, and the following appointments extend over six months:—Six house physicians, eight house surgeons, two obstetric and gynaecological house surgeons, two casualty medical officers, and two casualty surgical officers. Non-resident qualified clinical assistants are appointed to assist in the various out-patients departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, etc.—Three entrance scholarships, value £100, £50, and £25, and a University Scholarship, value £50 (for Oxford and Cambridge students), are awarded annually in September. The successful candidates are required to become general students of the school. A Freer Lucas Scholarship, value £126, for students of Epsom College, is awarded annually on the nomination of the headmaster. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 ss.; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley clinical prize, value £25; the Leopold Hudson prize, value 11 guineas; and the second year's exhibition, value 10 guineas. There are also numerous class prize examinations. In connection with the cancer investigation department, the following scholarships are awarded:—"Emden" Cancer Research Scholarship, value £100, tenable for three years; Richard Hollins Research Scholarship, value £105; Salters' Company Cancer Research Scholarship, value £100; and a Cancer Research Scholarship, value £60.

Fees.—The composition fee for general students is 135 guineas; for London University students, 145 guineas; for those who have passed the first examination for medical degrees, 120 guineas; those who have completed their anatomical and physiological studies, 70 guineas. The fee for dental students is 54 guineas. The fees may be paid by instalments.

The Amalgamated Students' Club includes the following:—The Medical Society, The Common Room Society, The Cricket Club, The Football Clubs, The Athletic Clubs, The Rowing Club, The Musical Society, The Chess Club, The Lawn Tennis Club, and The Hockey Club. The Athletic Ground which is eight acres in extent, is situated within easy access of the Hospital—at Park Royal. There is a Gymnasium within the precincts of the Hospital. A subscription to the Amalgamated Students' Club is payable by all General and Dental Students.

The Winter Session 1912-1913 will open on Tuesday, October 1st, at 3 p.m. The Introductory Address will

be given by W. S. Lazarus-Barlow, Esq., M.D., F.R.C.P.

ST. THOMAS'S HOSPITAL.—This Hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament, and contains 602 beds, in constant use. The school buildings, which are separated from the Hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Four hospital registrars, two at an annual salary of £100 each, and two at £50 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. Four resident house physicians, four house surgeons, eight casualty officers, two resident obstetric house physicians, and two ophthalmic house surgeons are appointed each six months, also out-patient officers, and clinical assistants in the special departments.

Scholarships, Prizes, &c.—Five entrance scholarships are offered for competition in July—*viz.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school, and two scholarships in arts giving free tuition for the first year of curriculum. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the First Professional Examination and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

Fees.—A system for payment of composition fees is in operation. Full details may be obtained of the Secretary.

UNIVERSITY COLLEGE HOSPITAL AND MEDICAL SCHOOL.—**Entrance.**—A student may enter the school as soon as he has passed the University of London Matriculation Examination, or one of the other qualifying preliminary examinations. In this case he will pursue his preliminary and intermediate studies at University College, and his final medical studies at University College Hospital Medical School. The student who has completed his preliminary and intermediate medical studies elsewhere, may enter the University College Hospital Medical School for his final medical studies only. Qualified medical men and others who can produce evidence of sufficient qualifications may be admitted to special departments for the purposes of research, or to hospital practice for certain definite periods.

University College Hospital now accommodates 305 in-patients, and possesses extensive out-patient and special departments.

Thirty-eight clinical appointments, eighteen of which are resident, are filled up by competition during the year, and are open to students at the hospital without extra fee.

The new medical school provides for lectures, demonstrations and practical work in all the final subjects of the medical curriculum. There are three lecture demonstration theatres for the teaching of morbid anatomy, bacteriology, and chemical pathology;

also rooms equipped for the teaching of operative surgery and surgical anatomy, and two large lecture theatres.

The Medical Society, founded in 1828 for promoting the study of medical and surgical sciences amongst students, and for social intercourse, has rooms set apart for reading and recreation, and there is a large gymnasium with baths attached in the school buildings.

Scholarships, &c.—Entrance scholarship of 135 guineas, and two of 80 guineas each, the subjects being anatomy and physiology; the Graham scholarship in pathology, £200 per annum; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; the Atchison scholarship, value £55, tenable for two years; Pilliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Fellowes gold and silver medals, the Liston gold medals, Alexander Bruce gold medal, Tuke medals for pathology, and other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study.

Composition Fees.—The Preliminary Scientific Course at University College, 26 guineas; Intermediate Course at University College, 58 guineas; final M.B. Course at University College Hospital Medical School, 80 guineas if paid in one sum, or 82 guineas paid in two instalments of 50 and 32 guineas.

WESTMINSTER HOSPITAL.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by, which afford accommodation for 150 students. The class rooms, museum, laboratories, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Qualified students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(a) Winter Session.—The Guthrie scholarship, £60; subjects, Latin, mathematics, English, and either Greek, French or German. Two University scholarships, £50 each; subjects, anatomy and physiology. Natural science scholarship, £60; subjects, same as for Preliminary Science of University of London. Natural science scholarship, £30; subjects, chemistry and physics. (b) Summer Session.—Governors' scholarship in Chemistry and Physics, £40, Two University scholarships as for Winter Session. (c) Prizes to be competed for by unqualified men. Chadwick prize in Medicine and Surgery, 20 guineas, for students of any year not exceeding fifth. Bird medal and prize, in Obstetric Medicine, £14, for students who have completed fourth winter session. Sturges prize in Clinical Medicine, about £6, clinical surgery prize, £5. Abrahams prize in Clinical Pathology, 5 guineas. And class prizes in the various subjects.

Fees.—(a) The Annual Composition Fee is 25 guineas. This includes the subscriptions for membership of the Clubs' Union. (b) For shorter periods or for single courses the fees may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s. each.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—The school is situated in Hunter Street, and the Royal Free Hospital is in Gray's Inn Road, close by. Students are prepared for the London University examinations and for the examinations of other Universities. A course of study is also arranged for the work required by the Royal Colleges of England, the Conjoint Colleges of Scotland and the Society of Apothecaries of London. The

Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in medicine, surgery, obstetrics, ophthalmology, and dermatology. Students hold clerkships and dresserships in each department.

Appointments.—House physicians, house surgeons, and a senior and junior resident obstetric assistant are appointed yearly. There are also non-resident appointments, including the anaesthetists and assistant anaesthetist, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

Fees.—The fee for the University of London course and the course for the Royal Colleges of England is £160 in one sum, or £170 if paid in five instalments. The fee for the course for the Scotch Colleges or Society of Apothecaries, including Elementary Science, is £140 in one sum, or £150 in four annual instalments. Particulars as to scholarships, &c., can be obtained from the Secretary and Warden, Miss L. M. Brooks, 8 Hunter Street, W.C.

LONDON SCHOOL OF TROPICAL MEDICINE.—The next session of the school commences on the 1st of October. The past year has been one of the most successful on record, and, for the session ending in July, 64 students entered. The course is so arranged as to equip men for the Cambridge Diploma in Tropical Medicine and Hygiene, the London Diploma in Diseases and Hygiene of the Tropics, as well as for the London University M.D. Special facilities are now afforded for advanced students in entomology, helminthology, and protozoology. The Wandsworth Scholarship of £350 and the Hon. Edward John Stanley Memorial Scholarship of £50 are awarded annually. The school provides three sessions each year. The buildings are being enlarged, and in the future it is hoped that there will be room for all who desire to take out the course. Arrangements are made in the neighbourhood for providing rooms where students can reside, and there is ample accommodation for all who desire to mess in the school.

INTRA-ACADEMICAL INSTITUTIONS IN LONDON.

THE ROYAL DENTAL HOSPITAL.—The teaching and hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital and school, which was opened seven years ago, is complete in every detail with modern appliances. The clinic of the hospital is unrivalled, no fewer than 105,000 operations being performed in one year. The following scholarships and prizes are open to all full term students:—Entrance scholarships, of the value of £50 and £25, being awarded in October. Subjects: Chemistry and Physics, Saunders scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks in a special examination of the subjects of the final examination for the Dental half of the L.D.S. A scholarship of £25, the subjects being dental mechanics and metallurgy. There is also an Entrance Scholarship of £25 open to those who have studied "Dental Mechanics" under the tuition of a private practitioner. Storer-Bennet research scholarship of the value of £50, awarded once in three years; the Alfred Woodhouse scholarship of £30, and the Robert Woodhouse prize of the value of £10, for practical dental surgery. Class prizes are awarded by the various lecturers. Provision is made for teaching Dental Mechanics, as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators. The school contains an excellent library and a well-arranged museum.

Fees.—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum, namely, two years' instruction

in Dental Mechanics and two years' hospital practice and lectures, is £150 if paid in one sum, or 150 guineas if paid in three instalments of 50 guineas each. For one year's instruction in Dental Mechanics the fee is 50 guineas. For one year's hospital practice, £21. For the courses in Chemistry and Physics for the Preliminary Science Examination, £10 10s. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

NATIONAL DENTAL HOSPITAL (The Dental Department of University College Hospital).—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, X-Rays Department, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental department of a general hospital and school. The winter session commences at the same time as at the medical school, on October 1st. The medical tutor holds special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for two years' hospital practice required by the full curriculum, including lectures, is £200.

For qualified medical men the two years' training in dental mechanics, required by the R.C.S. Curriculum, can be taken in the Mechanical Laboratory, and there is a "Composition Fee" including all the dental subjects of the curriculum of £120.

Medical students are admitted to the practice of the following Metropolitan general hospitals to which no medical school is attached, but each contains over 100 beds. Detailed particulars will be supplied on application to the various secretaries.

PRINCE OF WALES'S HOSPITAL, Tottenham.—This hospital contains medical and surgical wards and a ward for children, having in all 125 beds, with a very large out-patient department. There are special departments for gynaecological cases, diseases of the eye, ear, throat and nose, medical electricity and radiography, and skin diseases. It is authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees. (Post-graduates of both sexes are admitted to the practice of this Hospital.)

WEST LONDON HOSPITAL, Hammersmith Road, W.—(Only qualified medical men are admitted to the practice of this Hospital). This hospital contains 160 beds, and has an extensive out-patient department. Three house surgeons and three house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway Road, N.—This institution has been greatly enlarged, contains 182 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The Pathological Department has been extended and a Director of Clinical Pathology appointed. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

BETHLEM ROYAL HOSPITAL.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months,

and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM, Queen Square, W.C., contains, with its country branch, 200 beds and cots. It is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

LONDON TEMPERANCE HOSPITAL.—This Institution is situated in the Hampstead Road, and contains 100 beds, and is conducted, as its name implies, on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

METROPOLITAN HOSPITAL, Kingsland, N.E.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 123 beds, besides 18 beds at a convalescent home. It is a general hospital, with a large medical and surgical staff, in which various special departments for the treatment of diseases of the eye, throat, ear, diseases of women, etc., will be found.

SPECIAL HOSPITALS.

HOSPITALS FOR CONSUMPTION.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 333 beds in the two buildings. There are six house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. A special course of instruction in the diagnosis and treatment of pulmonary tuberculosis will be held from November 4th to 16th. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

MOUNT VERNON HOSPITAL, Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 120 beds, and at Northwood with 106 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 170 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.
